Total value	2,629,592	2,360,053

Monthly Patent List.

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

16,726. E. Theisen. Method of and apparatus for producing intimate frictional action between liquids and gases or vapours, by means of centrifugal force, for effecting either the evaporation of the liquids of the interchange of temperature between the liquids and gases, or the mixing of the gases with, or their separation from, the liquids. September 19.

17,301. D. W. Noakes. Improvements in gauges used for ascertaining the pressure in compressed gas cylinders and other reservoirs. September 28.

17,458. W. W. Fyfe. Improvements in and connected with furnaces and means for calcining and treating complex ores. September 30.

17,519. W. H. Westwood, E. T. Wright, and W. W. S. Westwood. Improvements in washes for washing gases. October 1.

17,824. W. Mather. See Class VII.

18,325. F. T. Bond. An appliance for making infusions or extracts of vegetable or other matters. October 13.

COMPLETE SPECIFICATIONS ACCEPTED.*

1891.

18,488. J. Sutton. See Class XVII.

18,959. A. Feldman. Distilling apparatus suitable for the treatment of ammoniacal liquors. October 19.

20,142. J. C. Mewburn.—From The Maschinenfabrik Grevenbroich. See Class XVI.

20,677. W. R. Jones. Furnaces. October 5.

20,788. E. Goedicke. Reverberatory furnaces. October 5.

21,157. J. Dawson. Thermometers. October 19.

21,730. M. F. Purcell and G. Purcell. Apparatus for the purification of gaseous fumes, air, and the like, and the deposition of solid particles therefrom. October 19.

22,089. P. Labric. See Class XVI.

1892.

7753. J. Morrison. Ejectors for ejecting water, thick or thin, or tar and ammonia water. October 5.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

16,694. B. Ratcliff. Improvements in or additions to carbon lamps or carbon burners for illuminating purposes. September 19.

16,750. F. Grein. Charging machine for gas retorts. Complete Specification. September 19.

17,067. H. Collet and M. Merichenski. Improvements in making gas, and a compound therefor. September 24.

17,262. R. M. Bidelman. Improvements in the manufacture of gas. Complete Specification. September 27.

17,394. H. E. Newton.—From R. N. Oakman, jun., United States. Improved apparatus for the manufacture of illuminating gas. September 29.

17,419. F. J. Collin. Improvements in coke furnaces. Complete Specification. September 29.

17,484. P. Jensen.—From H. Stierner and M. Ziegler, Germany. Process of and apparatus for working up organic fibrines of large and hardened form for the purpose of procuring tar, oil, paraffin, asphalt, pitch, heating and illuminating gases, and large coke. Complete Specification. September 30.

17,519. W. H. Westwood, E. T. Wright, and W. W. S. Westwood. See Class I.

17,644. J. A. Yeadon and W. Adgie. Improvements in retorts for the distillation of oil from shale or other analogous substances. October 4.

18,047. N. McFarlane Henderson, J. S. MacArthur, and E. Hunt. See Class III.

18,521. H. H. Lake.—From T. G. B. de Ferrari di G. B., Italy. Improvements in and relating to apparatus for burning petroleum, naphtha, and other liquid fuels in steam-boiler furnaces. Complete Specification. October 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

19,496. J. Lyle. The treatment of ingredients for the manufacture of fuel briquettes. October 19.

19,758. Sir G. Elliot, Bart., and J. McGowan, jun. Manufacture of coke. October 19.

20,780. A. Jabs. Method of manufacturing producer- and water-gas. October 5.

21,249. E. Drorg. Apparatus for charging inclined retorts for use in the manufacture of coal-gas, and for similar purposes. September 28.

1892.

6697. J. Morley. Treatment of ingredients and the manufacture of compound blocks for use as fire-lighters. September 28.

7708. J. C. Chandler. Apparatus for washing, purifying, and scrubbing gas. September 28.

12,762. E. A. Erb. Combustion of carbonaceous fuel. October 19.

16,322. C. Winter. Artificial fuel. October 13.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

APPLICATIONS.

17,484. P. Jensen.—From H. Stierner and M. Ziegler, Germany. See Class II.

18,017. N. McFarlane Henderson, J. S. McArthur, and E. Hunt. Improvements in or connected with the destructive distillation of oil-yielding or gas-yielding minerals, and the obtaining of products therefrom. October 10.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

16,814. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of triphenylmethan dyestuffs. September 20.

16,815. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of new basic colouring matters. September 20.

17,070. Read, Holliday, and Sons, Limited, and J. Turner. Improvements in the production of azo-colouring matters. September 24.

17,147. B. Willeox.—From F. von Heyden, Germany. Improvements in the manufacture of chloro-para-oxybenzoic acids. September 26.

17,546. H. H. Lake.—From K. Oehler, Germany. Improvements in the manufacture of colouring matters. October 1.

* See Note (*) on previous page.

17,673. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in the manufacture or production of dyestuffs. October 4.

17,674. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in the manufacture or production of colouring matters derived from anthraquinone. October 4.

17,770. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of new azo-colouring matters, and processes for dyeing and printing therewith. October 5.

18,081. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Reduction of blue to blue-green colouring matters of the triphenylmethan series. October 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

19,062. B. Willeox.—From The Farbenfabriken vormals F. Bayer and Co. Manufacture and production of colouring matters. October 19.

20,275. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik. Manufacture and production of azo-dyes, and of materials therefor. September 28.

21,717. B. Willeox.—From The Farbenfabriken vormals F. Bayer and Co. The manufacture and production of new derivatives of alizarin and its analogues. October 19.

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATIONS.

16,935. R. Cottam. An improvement for more effectually cleaning textile fabrics in the process of manufacture. September 22.

16,951. C. E. Wright. An improved method of treating silk textile fabrics for preventing the formation of mildew upon the same. September 22.

17,055. D. Donald. Improvements in the manufacture of jute yarns. September 24.

18,358. A. F. B. Gomess. A new or improved process for the treatment of textile vegetable fibres, and in apparatus connected therewith. October 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

17,325. G. E. Armstrong. Composition for treatment of fibres. September 28.

18,851. W. Golding. Compound of india-rubber and fibre formed by treating fibrous fabrics, yarns, cords, &c., with rubber, so that the fibrous material is permeated by the rubber, and the individual fibres are embedded therein, constituting a new manufacture to be called "Rubbric," and processes, apparatus, and machinery for producing the same. October 5.

19,710. F. G. Annison. Treatment of linen and other textile fabrics, applicable to the manufacture of show bills, show cards, posters, tablets, wall decorations and other purposes. September 28.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

18,031. T. Briggs and E. Webb. Improvements in apparatus for printing textile fabrics. October 10.

18,052. T. Lye and W. T. Lye. Improvements in the bleaching or dyeing of "chip," "straw," and "chip-plait," and "straw-plait." October 10.

18,395. S. W. Wilkinson and R. A. L. Hutchinson. An improved method or process of sizing fibrous materials. October 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

20,574. J. Longmore and R. Williamson. Dyeing silk and other fibres. October 5.

1892.

11,416. F. F. Grafton and W. Browning. Process for the production and fixation of colours in conjunction with aniline black upon woven fabrics. September 7.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

16,757. J. Rice. Improvements in or relating to the manufacture of sulphuric acid. September 20.

16,873. C. L. C. Berton. Improvements in the process of precipitating oxide of tin from solutions. September 21.

16,874. C. L. C. Berton. Improved process for the precipitation of tin from acid solutions containing same with other metals. September 21.

16,922. J. S. MacArthur. Improvements in obtaining cyanides. September 22.

17,216. H. C. Bull. An improved process for recovering sulphur from sulphurous acid and for obtaining bisulphide of carbon, and apparatus therefor. September 27.

17,228. W. P. Thompson.—From T. Mayer, Germany. A new or improved manufacture of double salts containing fluorine and an always constant amount of antimony. September 27.

17,240. A. V. Newton.—From A. Nobel, France. Improvements in the production of cyanides. September 27.

17,241. A. V. Newton.—From A. Nobel, France. An improved mode of producing nitrogen compounds. September 27.

17,661. H. H. Lake.—From E. Noriega, Mexico. See Class X.

17,824. W. Mather. Improvements in the dehydration of ammonia and other volatile liquids, vapours, or gases, and in apparatus therefor. October 6.

17,911. P. M. Justice.—From E. G. Acheson, United States. Improvements in and connected with carbonaceous compounds. October 7.

18,232. A. Vogt and A. R. Scott. Improvements in treating manganese nitrate for the recovery of nitric acid and manganese peroxide. October 12.

18,496. J. Morris. New or improved process for the production of crystals or crystalline masses. October 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

17,745. F. M. Lyte and C. H. M. Lyte. Production of chlorine conjointly with the purification of lead and the recovery of silver. October 19.

18,231. D. Rylands. Processes for producing carbonic acid gas. September 28.

18,481. J. E. Bott. Manufacture of salt. October 5.

18,693. W. Smith. See Class XIII.

18,959. A. Feldman. See Class I.

19,375. C. Hoefner. Manufacture of chlorine. October 19.

22,018. A. Vogt. Manufacture of nitric acid. October 12.

22,541. J. Brock and J. T. Marsh. Manufacture of carbonates of strontium and barium. September 28.

22,704. H. H. Lake.—From V. Hametelle. Apparatus for use in the concentration of sulphuric acid. October 19.

1892.

192. A. S. Caldwell. Apparatus for evaporating and incinerating spent or used alkaline lyes or similar waste products. September 28.

2415. J. Wetter.—From H. and E. Albert and Co. Process for obtaining alkali phosphates from neutral or acid alkali sulphates. October 19.

8276. La Société A. R. Pechiney et Cie. Apparatus for the manufacture of a mixture of hydrochloric acid gas and air. September 28.

10,450. E. J. Barbier. Process and apparatus for the production of neutral sulphate of soda and sulphuric acid from bisulphate of soda. October 12.

10,599. E. Lohmann. Process for producing pure carbonic acid gas. October 12.

15,275. W. Stones and R. Bardsley. Method and apparatus for the production of carbonic acid gas. October 5.

15,513. H. J. Haddan.—From P. Viscount Lambilly. New process for the production of the cyanides of the alkalis and alkaline earths by the simultaneous employment of a hydrocarbon and ammonia gases, with the addition, if desired, of free nitrogen. October 5.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

APPLICATIONS.

16,792. F. Shuman. Improvements in the method of and apparatus for manufacturing wire glass. Complete Specification. September 20.

17,042. A. Horsfall. Improvements in frits for the production of glazes, enamels, &c. applicable to china, earthenware, metals, &c. September 24.

17,848. P. Sievert. Process for producing flat objects of glass and means for carrying out such process. Complete Specification. October 6.

18,135. L. H. Pearce. Improvements in the manufacture of blown glass articles. October 11.

18,178. J. Wade, W. Wade, and H. Wallace. A new or improved process for decorating tiles. Complete Specification. October 11.

18,313. J. B. Adams. Improvements in the manufacture of spherical bodies from glass or the like, and apparatus therefor. October 13.

18,448. P. Sievert. Process and means for manufacturing glass pipes. Complete Specification. October 14.

18,510. J. C. Mewburn.—From E. F. W. Hirsch, Germany. Improvements in the process of and apparatus for melting glass composition in melting tanks or melting pots. October 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

18,230. D. Rylands. Furnaces or retorts used in the production of glass and for similar purposes. October 12.

19,777. T. C. J. Thomas. Construction of tank furnaces for the manufacture of glass. October 19.

20,280. Craven, Dunnill, and Co., Limited, and F. R. Smith. Manufacture of tiles and the like, and apparatus therefor. October 5.

20,861. J. E. G. Meran. A new product to serve as a substitute for pottery, for filtering purposes, and for the manufacture of tobacco pipes and the like. October 12.

1892.

16,241. J. C. Duntze. Process for producing colours on glass surfaces. October 19.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

16,717. J. C. Bloomfield. Improvements in the manufacture of plaster. September 19.

18,234. W. H. Pochin. An improved method of making Croft, Adamant, Victoria, and similar concrete paving slabs, kerbs, channels, window sills, steps, and tiles. October 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

17,050. J. U. Robertson.—From C. W. Kennedy. See Class XIII.

19,106. D. Ward. Making coloured stucco, coloured concrete blocks and tiles. October 12.

1892.

15,147. J. E. Keseling and C. Fuchs, jun. Artificial stone composition. September 28.

X.—METALLURGY, MINING, ETC.

APPLICATIONS.

16,800. J. Strap. A process for recovering copper and nickel from ores or matters containing these metals. September 20.

16,891. E. Ruck and F. N. Raggatt. Improvements in or relating to the smelting of zinc. September 21.

16,894. J. C. Montgomerie. Improvements in the extraction of gold and silver from ores or compounds containing the same. September 21.

17,081. A. Culley. A silver-plating compound. September 24.

17,206. J. Colley and T. Twynam. Improvements in the manufacture of ingot iron and steel. September 27.

17,339. G. F. Thomson. Improvements in or relating to the manufacture of iron and steel. September 28.

17,521. J. H. Darby. Improvements in or appertaining to furnaces for the manufacture of pig or cast iron. October 1.

17,576. W. Mills. Improvements in the manufacture of sodium. October 3.

17,619. J. D. Gilmour and J. Finlay. Improvements in the extraction of copper or other metals from ore. October 4.

17,661. H. H. Lake.—From E. Noriega, Mexico. Improvements in and relating to the preparation of reagents for working gold and silver ores. October 4.

17,692. E. H. Saniter. Improvements in or relating to the purification of iron or steel from sulphur. October 4.

17,694. J. W. Kynaston. Improvements in the extraction of bismuth, especially applicable to the treatment of the flue dust of copper works. October 4.

17,825. H. Imray.—From La Compagnie Anonyme des Forges de Chatillon et Commentry, France. A process for facilitating the fusion of mild steel and other refractory metals. October 6.

17,908. W. Smethurst. A new or improved furnace for the reduction or smelting of zinc, lead, silver, gold, and other ores. Complete Specification. October 7.

17,918. C. A. Netto, J. Pfleger, and L. Hausmann. Improvements in the production of easily separable metallic deposits. October 7.

17,928. C. H. Hubbell. An improvement in the manufacture of mineral wool. Complete Specification. October 7.

17,951. T. Twynam. Improvements in the recovery of tin from tin-plate scrap. October 8.

18,082. C. D. Abel.—From Harder Bergwerks-und Hütten-Verein, Germany. Process for the removal of manganese from pig iron, ingot iron, and steel. Complete Specification. October 10.

18,163. C. Allen and C. Davey. Improvements in the manufacture of cast iron and steel, and apparatus therefor. October 11.

18,275. M. Lewthwaite. An improvement connected with the treatment of metals in a fluid state. October 12.

18,292. H. M. Hyndman.—From J. Vandessluis, France. A new or improved process for the production of aluminium. October 12.

18,307. T. F. Bardour. Improved process for extracting gold, silver, and other metals from ores. October 13.

18,394. W. Mills. Improvements in the manufacture of aluminium and apparatus therefor. October 14.

18,494. J. M. Stuart and J. W. Cohen. Improvements in obtaining precious metals from their ores. October 15.

18,495. J. M. Stuart and J. W. Cohen. Improvements in the apparatus to be used in obtaining precious metals from their ores. October 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

16,273. J. H. Bibby. Process of smelting copper ores and furnaces or apparatus applicable therefor. September 28.

17,745. F. M. Lyte and C. H. M. Lyte. See Class VII.

18,990. J. Colley. Adding metallic and non-metallic substances to steel and iron. October 12.

20,461. E. K. Dutton.—From A. Mathies. Production of hollow steel ingots, and apparatus therefor. October 5.

21,114. E. Norton. Coating metals. September 28.

1892.

8612a. E. H. Saniter. Purification of iron. October 19.

15,058. E. Martin. Process for alloying the surfaces of metal wires, strips, plates, sheets, and the like. September 28.

15,248. J. W. Sutton. Wet process for the extraction of gold or silver, or both, from pulverised ores or other finely-divided material, and apparatus therefor. September 28.

15,584. J. W. Chenall. Extraction of metals from their ores. October 5.

16,173. J. T. Wainright. Process of reducing un-smelted ore, including roasted ore, furnace cinders, and like material. October 19.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

16,822. T. Craney. Improvements in electrolytic apparatus. Complete Specification. September 20.

16,866. A. Müller. Improvements in electrode-plates for secondary batteries. September 21.

16,878. E. Bailey and J. Hall. Improved plates for secondary batteries. September 21.

16,892. D. Tommasi. Process and apparatus for the extraction, separation, and refining of metals by electrolysis. Filed September 21. Date applied for, April 1, 1892, being date of application in France.

16,893. D. Tommasi. Process and apparatus for the extraction, separation, and refining of metals by electrolysis. Filed September 21. Date applied for, May 21, 1892, being date of application in France.

16,919. J. Swinburne. Improvements in and connected with dynamo-electric machinery, alternating current motors, transformers, manufacture of ozone and oxide of nitrogen, recovery of tin from scrap, electro-plating with aluminium. September 22.

17,099. H. T. Barnett. An improvement in carbon electrodes. September 24.

17,169. C. Kellner. Improvements in or relating to the electrolytical decomposition of metallic salts, and in apparatus therefor. September 26.

17,222. W. P. Thompson.—From C. L. Coffin, United States. Improvements in or relating to electric metal working or welding. Complete Specification. September 27.

17,223. W. P. Thompson.—From C. L. Coffin, United States. Improvements in or relating to welding or working metals electrically. Complete Specification. September 27.

17,224. W. P. Thompson.—From C. L. Coffin, United States. Improvements in apparatus for electrically heating and working metal. Complete Specification. September 27.

17,225. W. P. Thompson.—From C. L. Coffin, United States. Improvements in the method of and apparatus for electrically welding metals. Complete Specification. September 27.

17,226. W. P. Thompson.—From C. L. Coffin, United States. Improvements in the method of and apparatus for welding or heating metals electrically. Complete Specification. September 27.

17,227. W. P. Thompson.—From C. L. Coffin, United States. Improvements in or relating to electrically welding or heating metals. Complete Specification. September 27.

17,246. T. J. D. Rawlins. Improvements in or connected with electric primary batteries. September 27.

17,348. R. J. Crowley. Improvements in or relating to batteries. September 28.

17,466. H. C. Bull and Gustavus, Baron de Overbeck. An improved electro-metallurgical process. September 30.

17,922. F. King and E. Clark. Improvements in secondary batteries. October 7.

17,930. J. Hirshfeld, W. Morison, A. P. Morison, and W. Wright. Improvements in secondary batteries. October 7.

17,931. J. Hirshfeld, W. Morison, A. P. Morison, and W. Wright. Improvements in battery compounds. October 7.

18,037. W. C. Mountain. Improvements in electric welding apparatus. October 10.

18,039. J. Hargreaves and T. Bird. Improvements in electrolytic cells and diaphragms. October 10.

18,215. J. Muter. Electro-plating ceramic, vitreous, and similar non-conducting substances. October 12.

18,280. H. Gardnep.—From E. Francke, Germany. Improved construction of grid plates for holding the active material in secondary batteries. October 12.

18,516. E. N. A. Picard and J. A. Tanière. Improvements in and relating to the electro-deposition of metals. Complete Specification. October 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

16,934. H. H. Lake.—From P. Kennedy and C. J. Diss. Secondary or storage batteries. October 5.

16,938. H. H. Lake.—From P. Kennedy and C. J. Diss. Secondary or storage batteries. October 5.

18,256. A. S. Ford.—From H. Pottier. Process for the electro-deposition of metal upon the surface of glass, porcelain, china, earthenware, and other materials. October 12.

19,704. J. C. Richardson. Application of depolarisers in electrolysis. October 19.

19,775. A. Breuer. Diaphragms for electrolytic decomposing apparatus. October 5.

20,312. J. M. Moffat. Form of electrical battery cells, boxes, or vessels. September 28.

1892.

14,089. C. C. Lesenberg and J. von der Poppenburg. Dry galvanic batteries. October 5.

14,814. E. P. Usher. Storage batteries. October 5.

14,816. E. P. Usher. Electric battery plates. October 5.

15,477. A. F. W. Kreinsen. Means for and method of melting metals and other materials by electricity. October 19.

15,799. E. Nunan and J. W. Nelson. Galvanic batteries. October 9.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

APPLICATIONS.

16,767. W. Mills. Improvements in and relating to the recovery of soap and suint from wool-grease. September 20.

16,827. W. R. Lake.—From W. T. Cutter, United States. Improvements relating to the cleansing of or extraction of

fatty substances from wool and the like, and to a method of clarifying the solvent used therefor. Complete Specification. September 20.

16,954. A. G. Petty. Improvements in the steam treatment of oils and fats for purifying or distilling purposes. September 22.

17,230. J. C. Lahusen. Improvements in or relating to the production of a neutral wool-grease from suint or wool washings. September 27.

17,478. J. C. Fell.—From H. Heller, Austria. See Class XVIII.—C.

18,086. E. Hill, F. W. J. Webb, A. W. Machouachie, and S. Roper. Improvements in cleaning and renovating compositions. October 10.

18,451. M. Perls. An improved manufacture of soap. October 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

18,224. W. Mills. Bleaching, deodorising, and purifying fats and oils, and apparatus therefor. September 24.

20,590. E. J. T. Digby. Manufacture of soap. October 5.

1892.

14,405. H. H. Lake.—From O. P. Amend and J. H. Macy. Desulphuration of oils. October 5.

15,012. J. Trent and G. Henderson. Process of extracting, purifying, and saving the fat or grease from wool, and for cleaning the wool by the use of benzole (benzene) or any other spirituous liquid suitable for dissolving the fat or grease. September 28.

15,899. J. C. Decker. Oil for general painting. October 12.

16,018. W. H. Horton and E. M. Taylor. Dry soap or soap powder for use for certain purposes. October 12.

XIII.—PAINTS, PIGMENTS VARNISHES, AND RESINS.

APPLICATIONS.

17,739. R. Hutchison. Improvements in treating or preparing gutta-percha and rubber for various purposes. October 5.

17,808. M. N. d'Andria. Improvements in the manufacture of pigments. October 6.

17,872. R. J. White and J. C. Martin. Improvements in oil and water colour paints. October 7.

18,346. H. C. Standage and C. Smith. Improvements in the manufacture of pigments. October 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

17,050. J. U. Robertson.—From C. W. Kennedy. Processes for making plastic compounds or compositions. October 19.

18,693. W. Smith. Preparation of acetate of ammonia for use in the manufacture of white lead by the acetate of ammonia process. October 12.

18,709. T. H. Cobley. Treatment of lead ores and the production therefrom of white lead, salts of and colours of lead, as also simultaneously zinc white. October 5.

18,895. C. H. Matthews.—From E. S. Matthews. Compound for coating ships' bottoms, piles, and structures subject to the influence of sea-water. October 5.

21,203. J. C. Chapman.—From J. M. James. A process of and materials for coating metallic surfaces for the prevention of fouling and corrosion, and reducing surface friction. October 19.

1892.

14,656. A. J. Smith. Manufacture of white lead. October 12.

14,794. G. D. Coleman. Process and apparatus for the manufacture of white lead and other lead pigments. September 28.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATION.

18,143. C. A. Jensen.—From W. M. Walters. A new or improved putty or marine glue. October 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

20,755. W. P. Thompson.—From F. Kranseder and A. Lentsch. Apparatus or appliances for use in drying sheets of glue, gelatin, and the like. September 28.

21,774. G. van Haecht and C. Obozinski. A new process for tanning, and apparatus relating thereto. October 19.

1892.

15,630. E. Brand. Manufacture of animal glue. Oct. 5.

XV.—AGRICULTURE AND MANURES.

APPLICATION.

18,129. A. Macarthur. An improved fertiliser. Oct. 11.

XVI.—SUGARS, STARCHES, GUMS, ETC.

APPLICATION.

16,810. G. J. Epstein. The treatment of residue from breweries, distilleries, or starch factories, or of grain, flour, or other matter containing gluten or albuminates or gluten or albumen and starch for the obtainment of useful products therefrom. September 20.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

20,142. J. C. Mewburn.—From The Maschinenfabrik, Grevenbroich. Centrifugal machines or hydro-extractors for extracting sugar juice from crystals, and for other purposes. September 28.

22,089. P. Labrie. Apparatus for evaporating saccharine or other solutions or liquids. October 19.

1892.

15,897. A. Rümpler. Process and apparatus for the production of invert sugar and dextrose. October 12.

XVII.—BREWING, WINES, SPIRITS, ETC.

APPLICATIONS.

16,810. G. J. Epstein. See Class XVI.

16,896. F. E. V. Baines. Improvements in the treatment of rice or other grain for the obtainment of a product suitable for use in brewing and distilling, and for other purposes. September 21.

17,258. E. Adam. Improvements in malt beverages. Complete Specification. September 27.

17,927. R. Hges. Improvements in the method of and apparatus for distilling mash for the purpose of obtaining highly concentrated fusel oil and purified alcohol. Complete Specification. October 7.

18,332. W. H. Willis. An improved apparatus for taking samples of beer from fermenting vessels. October 13.

18,370. A. T. Harris. Harris's patent rectifier. October 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

17,374. J. Takamine. Production of alcoholic ferments, and of fermented liquors thereby. October 19.

17,395. J. Hillyard and E. Dugdale. Manufacture of beer and porter or like beverages. October 12.

18,488. J. Sutton. Process for filtering beer and other liquids, and apparatus therefor. October 19.

25,566. W. P. Thompson.—From O. E. Nycander and G. Francke. Process for the production of yeast and spirit by the employment of ozonised air, or oxygen. October 19.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

APPLICATIONS.

A.—Chemistry of Foods.

18,064. J. Berlit. New or improved manufacture of a substance or composition suitable for use as a substitute for cocoa. October 10.

B.—Sanitary Chemistry.

16,838. J. Burton. Improvements in the means for drying, burning, and consuming the refuse and garbage of towns usually burnt in destructor furnaces. September 21.

17,006. W. D. Scott-Moncrieff. Improvements in or relating to the treatment of sewage. September 23.

17,255. C. G. Matthews and F. E. Lott. Improvements in or relating to the treatment of sewage. September 27.

17,302. A. P. I. Cotterell. An appliance for facilitating withdrawal of sludge or deposit in sewage tanks, applicable also to clarifying water and other liquids. September 28.

17,815. V. J. C. Boulengier. Improvements relating to the disinfection of cesspools and the utilisation of the disinfected matter. Complete Specification. October 6.

18,317. J. Watts. Improvements in apparatus for generating and applying fumes, smoke, or vapours for disinfecting, deodorising, or fumigating purposes, or for the testing of pipes or passages by what is known as the smoke test, or for analogous purposes. October 13.

C.—Disinfectants.

16,807. W. Cooper. An improved disinfectant, insect destroyer, and deodoriser combined. September 21.

17,178. J. C. Fell.—From H. Heller, Austria. An improved disinfecting soap. September 30.

18,198. J. McHardy and M. E. A. Wallis. Improved disinfecting toilet-paper. October 15.

COMPLETE SPECIFICATIONS ACCEPTED.

A.—Chemistry of Foods.

1891.

21,706. O. Imray.—From The Farbwerke vormals Meister, Lucius, und Brünig. Process for preserving organic substances and for disinfection. October 19.

1892.

14,349. G. Barker.—From R. B. Beaumont. Gelatinous food products. October 19.

B.—Sanitary Chemistry.

1891.

17,769. E. Grimshaw. A new or improved compound for the precipitation and purification of sewage and other waste water, and drinking water. October 5.

19,157. E. Grimshaw and H. Grimshaw. The purification of waste effluent waters from manufacturing processes. October 12.

19,739. T. Wardle. Wardle's patent process for the treatment of sewage and other refuse matters. October 19.

22,442. J. Hanson. Treatment of sewage and other foul liquid or semi-liquid matters for the clarification, disinfection, and deodorisation thereof. October 19.

1892.

9685. C. H. G. Harvey. Manufacture of a porous magnetic ferric oxide filtering medium. September 28.

C.—Disinfectants.

1891.

21,706. O. Imray.—From The Farbwerke vormals Meister, Lucius, und Brünig. See Class XVIII.—(C.)

XIX.—PAPER, PASTEBOARD, Etc.

APPLICATION.

18,498. J. McHardy and M. E. A. Wallis. See Class XVIII.—(C.)

COMPLETE SPECIFICATION ACCEPTED.

1891.

17,536. S. Edwards. Manufacture of corrugated paper. October 12.

XX.—FINE CHEMICALS, ALKALOIDS ESSENCES, AND EXTRACTS.

APPLICATION.

16,942. W. P. Thompson.—From R. Campani, Italy. Improved process for extracting iodine from natural saline waters, mother-liquids, or other liquids containing iodine. Complete Specification. September 22.

COMPLETE SPECIFICATION ACCEPTED.

1891.

22,787. C. Fahlberg. Production of pure saccharine. October 12.

XXI.—PHOTOGRAPHIC PROCESSES AND MATERIALS.

APPLICATIONS.

16,778. D. McNae. An improved process of colouring pictures, especially applicable to photographs. September 20.

17,723. A. Radcliffe and the Sun Camera Co., Limited. Improvements in print washers used by photographers. October 5.

17,766. R. G. Williams. Improvements in photographic developing solutions. October 5.

17,767. R. G. Williams. Improved method of and apparatus for developing exposed photographic plates in day-light. October 5.

17,768. R. G. Williams. Improved solutions for toning photographic prints. October 5.

XXII.—EXPLOSIVES, MATCHES, Etc.

APPLICATIONS.

16,993. G. C. Baker. Improvements in and relating to ammunition. September 23.

17,305. T. P. Palmer. An improvement in matches. September 28.

17,525. G. Gersersdorfer. Manufacture of composition to be used in substitution for wood for match sticks for fire-lighters and torches. October 1.

18,183. A. V. Newton.—From A. Nobel, France. Improvements in the production of nitrogen compounds. October 11.

18,277. H. J. Haddan.—From The American Carrier Rocket Co., United States. An improved dynamite rocket. Complete Specification. October 12.

18,488. R. T. Plimpton and M. W. Travers. An improved manufacture of detonating compound. October 15.

COMPLETE SPECIFICATION ACCEPTED.

1891.

19,267. W. P. Thompson.—From E. Landauer. Manufacture of explosive substances. September 28.

XXIII.—ANALYTICAL CHEMISTRY.

COMPLETE SPECIFICATION ACCEPTED.

1891.

20,956. W. Johnstone. Detection of foreign fats in butter. October 12.

THE JOURNAL OF THE Society of Chemical Industry:

A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 11.—Vol. XI.]

NOVEMBER 30, 1892.

[Non-Members 30/- per annum; Members
21/- per Set of extra or back numbers;
Single Copies (Members only) 2/6.

The Society of Chemical Industry.

Past Presidents:

Sir H. E. Roseoe, M.P., LL.D., V.P.R.S.	1881—1882.

NOTICES.

Foreign and Colonial Members are reminded that the subscription of 25s. for 1893, payable on January 1st next, should be sent in good time to the Treasurer in order to ensure continuity in the receipt of the Society's Journal. Any changes of address to appear in the new List of Members now in course of preparation, should reach the General Secretary not later than January 15th, 1893.

Post Office Orders should be made payable at the General Post Office, London, to the Honorary Treasurer, E. Rider Cook, and should be forwarded to him at Bow, unless it be desired to notify a change of address.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Secretary is prepared to offer 5s. apiece for copies of the Society's Journals for January 1883 in saleable condition.

LIST OF MEMBERS ELECTED, 23rd NOVEMBER 1892

Birkell, H. B., P.O. Box 962, Johannesburg, S.A.R., mining engineer.

Crenshaw, S.D., Crenshaw Building, Richmond, Va., U.S.A., chemical manufacturer.

Finlay, Kirkman, c/o Milne and Co., 123, Bishopsgate Street, E.C., East India merchant.

Gibbs, R. D., 140, Manor Street, Clapham, S.W., works manager.

Hamaguchi, K., Chōshi, Chibaken, Japan, soy manufacturer.

Johnson, Albert C., 2106, E. Baltimore Street, Baltimore, Md., U.S.A., chemical engineer.

Kellie, Jas. M., Straiton Oil Works, Loanhead, N.B., chemist.

Lester, J. H., 51, Arcade Chambers, St. Mary's Gate, Manchester, analytical chemist.

McArthur, Thos., Cairndhu, Kirklee Road, Glasgow, drysalter and dyewood manufacturer.

McBretney, E. G., 24, Eastfield Road, Castleford, Yorks., bottle works chemist.

Madden, W. J. H., 7, Montalto, South Parade, Belfast, wholesale druggist.

Pope, Frank, 40, Pearl Street, Cambridgeport, Mass., U.S.A., chemist.

Salmon, Edgar H. R., Cachoeira, Rio Grande do Sul, South Brazil, analytical chemist.

Sloan, Earle, Charleston, S. Carolina, U.S.A., chemical engineer.

Smith, Ernest A., Metallurgical Laboratory, Royal College of Science, South Kensington, S.W., assistant instructor in assaying.

CHANGES OF ADDRESS.

Best, Dr. T. T., 1/o Gamble and Sons; St. Helens, Lancashire.

Billing, H. S., Journals to 5, Regent Terrace, Plympton, South Devon.

Breckon, J. R., 1/o Fawcett Street; 53, John Street, Sunderland.

Brown, F. W., 1/o Warminster; 11, Bleuheim Terrace, St. John's Wood, N.W. (*temp.*)

Chaney, H., 1/o Kolar Road; Mysore Gold Mining Co., Ltd., Oorgaum, Mysore, South India.

Dunn, Jno., 1/o South Kensington; Morgan Academy, Dundee.

Dyson, Sept., 1/o Leeds; 14, West Bank, Heaton, Bradford, Yorks.

Ellis, Alexander, Journals to Skelton-in-Cleveland, Yorks.

Entwisle, E., 1/o Pendleton; Woodlands, Ashton-upon-Mersey, Cheshire.

Francis, Wm., jun., 1/o Chili; 7, Shaftesbury Square, Belfast.

Griffith, D. Agnew, 1/o Commercial Court; c/o Titan Soap Co., Lydia Ann Street, Liverpool.

Haake, C. Napier, Journals to "Chief Inspector of Explosives," Department of Trade and Customs, Melbourne, Victoria.

Hersam, E. A., 1/o Boston; State University, College of Mines, Berkeley, Cal., U.S.A.

Holloman, F. R., 1/o Leyton; 54, Russell Road, Custom House, E.

Kerry, W. H. R., 1/o Liverpool; Wheatlands, Windermere.

Kingdon, J. C., 1/o Myeene Road; Devonshire House, Hunter Road, Westcombe Park, S.E.

Leather, Dr. J. W., 1/o Preston; Land Revenue and Agricultural Department, Government of India, Calcutta.

Leese, Jos., 1/o Birkdale; 3, Lord Street West, Southport.

Love, Dr. E. G., 1/o Columbia College; 69, East 54th Street, New York, U.S.A.

McFarlane, R. E., 1/o Port Talbot; 92, Cardigan Terrace, Heaton, Newcastle-on-Tyne.

Munroe, Prof. C. E., 1/o Rhode Island; Columbian University, Washington, D.C., U.S.A.

Palmer, Thos., 1/o London; c/o Mon Van Cutsem and Co., Soignies, Belgium.

Peniston, A. H., 1/o Upton; Lyndhurst, Theydon Bois, Essex.

Perkin, A. G., 1/o Manchester; 8, Montpelier Terrace, Woodhouse Cliff, Leeds.

Perkin, Dr. W. H., jun., 1/o Edinburgh; Fairview, Wilbraham Road, Fallowfield, Manchester.

Redwood, I. J., 1/o 141; 104, Kent Street, Brooklyn, N.Y., U.S.A.

Rideal, Dr. S., Journals to Hotel Culm, St. Moritz, Engadine, Switzerland (*temp.*)

Saint, W. J., Journals to Reuterstrasse 2A, Poppelsdorf bei Bonn, Germany.

Schweich, E., 1/o Northwich; Poste Restante, Kingston, Jamaica.

Death.

W. Ramsay.	Frank Wilson.

Hon. Local Secretary: John Heron,
Ellerdale, Cottenham Park, Wimblesdon.

SESSION 1892-93.

Meeting held Monday, 7th November 1892.

MR. WM. THORP IN THE CHAIR.

IN opening the proceedings, the CHAIRMAN said that he would like to give a word of explanation as to why they had met there. The Chemical Society had (not a moment too soon) taken in hand the re-decoration and re-arrangement of its rooms. The work had been in hand for some months, and was now in a forward state, but the electric light had not been connected, and, consequently, they could not occupy their old quarters. The theatre in Jermyn Street and that of the Royal Institution being already occupied, they had, by the kind influence of the President, obtained the use of the rooms where they now met.

THE FORMATION OF NITROUS OXIDE AND A NEW METHOD OF PREPARATION.

BY WATSON SMITH.

Lecturer in Chemical Technology in University College, London.

NITROUS oxide has been, until within the last few years, chiefly a curiosity, because of its chemical and physiological properties. It is only comparatively recently that it has assumed distinct importance as an anæsthetic. Nitrous oxide was discovered by Priestley in 1776, and called by him "dephlogisticated nitrous gas." The associated Dutch chemists examined it in 1793, and proved that it was a compound of nitrogen and oxygen. For a full investigation of its properties we are indebted to Sir H. Davy, who published a full series of experiments on it in 1800, and he gave it its present name, "nitrous oxide." It appears that both Priestley and the Dutch chemists jumped to the conclusion that nitrous oxide was irrespirable, but it was Davy who, with characteristic boldness, inspired a quantity of it and showed that it possessed the peculiar physiological properties now so familiar to all chemists. I have spoken of Davy's characteristic boldness; it would have inevitably cost him his life, as the late Professor Thomas Thomson pointed out in his excellent, but now old, system of chemistry, on a subsequent occasion,—when he essayed to inhale nitric oxide gas, by first emptying his lungs of air, and then calmly attempting to inspire the colourless nitric oxide direct from a gas-receiver. Davy's rash desire was anticipated by a spasm of the epiglottis, which, whilst very painful, still effectually prevented the entrance of the gas into the lungs, and so saved Davy from otherwise inevitable asphyxia.

The two old methods for the production of nitrous oxide depend upon two reactions: the *first*, the reduction or deoxidation of nitric acid and other higher oxygen compounds, the *second*, by the decomposition of nitrate of ammonium by heat, where a complete resolution of the compound takes place, with formation of water (steam), and nitrous oxide. A *third*, not a success, was by the decomposition of a mixture of salts.

DEOXIDATION OF NITRIC ACID.—The deoxidation process, so far as I can make out, was the first one known, and was effected by treatment of nitric acid diluted with five or six times its weight of water, with such metals as copper, zinc, or tin. The gas obtained was not pure. Another deoxidant proposed was ammonium chloride, according to Miller (*Elements Inorganic*, 1864, 97). This is L. Smith's process, and it is said that the gas is contaminated with small quantities of chlorine and nitrogen.

Another deoxidant is stannous chloride dissolved in hydrochloric acid. Campari (*Comptes rend.* 1888, 1569) deoxidises nitric acid as follows:—A mixture of 5 parts of stannous chloride, 10 parts hydrochloric acid (sp. gr. 1.21) and 0.9 parts of nitric acid (sp. gr. 1.38) is heated to boiling, when it is claimed pure nitrous oxide is evolved in a regular stream. Any alterations in the proportions may cause explosions. The last statement spoils that of the "evolution of the pure gas in a regular stream!" Millon states that copper treated with nitric acid of sp. gr. 1.217 yields nitrous oxide mixed with a small quantity of NO, if the temperature be kept below -10° .

METHODS OF PREPARATION DEPENDING UPON THE DEOXIDATION OF LOWER OXIDES OF NITROGEN.

DEOXIDATION OF NITROGEN TRIOXIDE, N_2O_3 .—Sir H. Davy exposed "common nitrous gas"—I presume, N_2O_3 —for a few days to the action of iron filings, or to that of various other deoxidising agents. He adds the caution that "some nicety and experience are necessary, that the decomposition may be suspended before it has gone too far, when nitrogen gas will be obtained, and he recommends the use of potassium sulphite, which is incapable of decomposing nitrous oxide.

DEOXIDATION OF NITRIC OXIDE.—Nitric oxide gas is mixed with sulphuretted hydrogen, dry or moist "liver of sulphur" (mainly K_2S_3), moistened iron or zinc filings, hydrated ferrous sulphide, solutions of alkaline or earthy sulphites, or stannous chloride. By passing NO through a solution of sulphurous acid or an acid sulphite.

DECOMPOSITION OF HYDROXYLAMINE.—Silver nitrate ($AgNO_3$) with $NH_2OH + aq.$ forms metallic silver, nitrous oxide, and nitrogen. Iodine quickly decomposes NH_2OH and its salts to N_2O and H_2O , with collateral formation of HI.

Ferric sulphate is reduced to $FeSO_4$ with evolution of N_2O .

Sodium nitrate causes evolution of N_2O from—
 $2 NH_2OH \cdot H_2SO_4$ hydroxylamine sulphate.

DECOMPOSITION OF SALTS.

DECOMPOSITION OF NITRO-SULPHATE OF AMMONIA BY HOT WATER.—The most remarkable and probably least known decomposition of a salt which yields pure nitrous oxide is that of Pelouze's so-called *Nitrosulphate of Ammonia*, or, as Gmelin has it, "Sulphite of nitric oxide and ammonia." This salt is prepared by mixing a concentrated solution of ammonium sulphite with five times its volume of aqueous ammonia, cooling with ice, and then passing nitric oxide gas through the liquid. Crystals of the "nitrosulphate" are deposited. These are collected, washed with aqueous ammonia, and dried between folds of blotting paper. The salt is soluble in cold water, but on heating the solution decomposition sets in with brisk evolution of pure N_2O .

Decomposition of Nitrate of Ammonium by Heat.—This is the process known, I may now say, to every school boy, though I do well recollect a time, about 1857, when sundry play-books for boys recommended as a process for the preparation of "laughing-gas" the treatment of copper turnings with dilute nitric acid and collecting the gas in a

bladder. Then whilst closing the nostrils with the fingers of one hand, and holding the bladder with the other, the gas was to be inhaled. The books in question contained no record of any names with addresses of boys who had tried the experiment, and had really laughed in accordance with the description of pleasing symptoms which were to follow the inhalation; but I anticipate more wry faces and choking sensations were the leading features of such perilous experiments. I have no doubt our friend Dr. Alder Wright could tell us something on this subject, for he has been re-writing and rehabilitating a science play-book, and has now presented to the public one which is doubtless the best of the kind ever written.

The mode of decomposition of nitrate of ammonium by heat has become a matter of great interest recently, since that salt is now so much used in explosives. With regard to the melting point, this is stated in Watts' Dictionary to be about 152°C ., decomposition commencing at 210°C ., and becoming explosive about 300°C . According to Pleischl (Gmelin's Handbook, Vol. II. 490) the salt fuses imperfectly at 56° , perfectly at 108°C .; at 150° it evolves white fumes condensing in drops; at 175° it effervesces slightly; at 225° rapidly; at 238° it begins to evolve nitrous oxide and at 250° the gas is evolved in abundance. According to Legrand, at 180°C . the salt "bails" without being decomposed, decomposition not beginning until between 190° and 200° . Dr. Henry, in his Elements of Chemistry of 1810, states, on the authority of Davy, that at 316°C . (600°F .) the salt explodes and is entirely decomposed, and hence was formerly called "*Nitrum flammans*." It was Berthollet who first examined the nature of this decomposition.

According to Miller (Elements Inorganic, 1864, 459) the salt melts at 108°C ., and at 249° undergoes complete decomposition. We have thus rather a variety of melting and decomposition points.

	Melting Point.	Incipient Decomposition.
	$^{\circ}\text{C}$.	
Watts' Dictionary (Morley and Muir).....	152	210°C .
Pleischl (Gmelin).....	108	175° (begins to effervesce), at 225° (effervescence rapid), at 238° (begins to evolve N_2O).
Legrand.....	..	180° (bails without decomposition). Between 190° and 200° decomposition begins.
Watson Smith.....	153	Between 170° and 180° ; 205° N_2O first evolved distinctly over water; freely at 215° ; on cooling then continues at 180° , though slowly.
Biedermann's Chemiker-Kalendar.	..	At 170° begins to decompose.

On heating pure ammonium nitrate in a bulb apparatus, such as is used in distillations, the salt was found by me to soften at 145° and fuse at 160°C . mean = 152°C . Decomposition with slight effervescence began at about 170°C ., and nitrous oxide gas first came off over water at 205°C . I observed no such phenomenon as Pleischl describes of effervescence or boiling, without evolution of nitrous oxide. At 215°C . the evolution was tolerably active. On dropping the temperature to 180°C . it was found possible to continue the decomposition with slow evolution over water even at this temperature, though of course very slowly, yet undoubtedly with evolution of nitrous oxide. The water was cold. The bulb apparatus used was heated in a paraffin bath, and with thermometers in the fused salt and in the oil-bath as well. The decomposition of the salt at 215°C . was not accompanied by such exothermic effect as tended to cause the reaction to become self-accelerating or to "run away with one," if I may use the expression, but at 240°C . the evolution became vigorous and decidedly strong exothermic action was so manifested as soon to become uncontrollable, the thermometer rising rapidly towards 300°C . There thus appears to be a kind of equilibrium below which a slower evolution can be maintained, but over which it is upset, and the increments of exothermic force

are added in rapid progression, no doubt ever tending to the explosion point, which means an ultimate point of another and more drastic and complete reaction, in which oxygen, nitrogen, and steam are formed. So much for the ammonium nitrate method.

DECOMPOSITION OF MIXED SALTS.

Sal-ammoniac and Nitre.—The only method I know of in the text books is that of Grouvelle (*Ann. Chim. Phys.* 17, 351), who proposed to prepare nitrous oxide by heating a mixture of three parts of nitrate of potassium with one part of ammonium chloride. Pleischl states that by this means a mixture of chlorine, nitrogen, and nitric oxide is evolved, containing a small quantity of nitrous oxide. Soubeiran (*J. Pharm.* 13, 321, and *Pogg.* 13, 282) states that not a trace is formed. I have tried the method, and can testify to the abundance of chlorine and nitric oxide, but I could detect no nitrous oxide, though I will not say that absolutely none was formed.

Ammonium Sulphate and Nitre.—I will now pass on to the results of some attempts of my own to prepare nitrous oxide. About a year and a half ago it occurred to me to try if it was possible to ignite sulphate of ammonium or sal-ammoniac by dropping small pinches of it in the dry state into fused sodium nitrate, the hydrogen of the ammonia forming the combustible material, and being directly fired by the loosely combined oxygen of the nitrate. This was easily done. When, however, the sulphate was damp, the steam developed produced such local cooling effect that another phenomenon appeared instead of the flashes of fire, viz., evolution of red nitrous fumes. The experiment is easily shown in an iron or platinum dish, the crystals of $(\text{NH}_4)_2\text{SO}_4$ floating about in a blazing condition, just like bits of sodium burning upon water. On heating a mixture in equivalent proportions of the dry salts in a pulverised condition, viz., sulphate of ammonium and nitrate of soda, it was found that it was possible to obtain a large yield of very pure nitrous oxide gas. The reaction proceeded very smoothly and without tendency to any danger of explosive action, even on reaching higher temperatures at the close of the experiment.

The yield of nitrous oxide was slightly behind that obtained from an equivalent amount of nitrate of ammonium, in the proportion of about 2.6 : 3 by volume, but to set against this, besides the residue of sodium sulphate, is the convenience of safety in the moderate action that goes on in the retort, and the fact that the average cost of raw materials employed in the mixture is about 9l. to 10l. per ton to day, as against about 40l. per ton for ammonium nitrate.

In an American Specification, No. 173,961, February 22, 1876, relating to explosives, a certain Mr. Johnston states that he has actually formed some nitrate of ammonium by fusing together dry nitrate of soda and sulphate of ammonia, but he does not say that he ever extracted the nitrate of ammonia, or how he did so, or how demonstrated its presence. One thing is certain, you cannot properly fuse the mixture without evolution of N_2O , and another thing equally certain is you cannot get both N_2O and also nitrate of ammonium.

We have seen that the melting point of nitrate of ammonium is about 153°C ., and that incipient decomposition is observed at about 180°C ., and that at 205° nitrous oxide is first distinctly evolved and may be collected over water. Now, the melting point of nitrate of soda is close upon 316° (Carnelly), whilst that of sulphate of ammonium is decidedly not 140°C ., as stated in Gmelin, Vol. 2, 462, and all the text-books; also in Biedermann's Chemiker-Kalendar. Sulphate of ammonium softens and finally melts when considerably decomposed by heating up at nearly 330°C . That is the plain fact. Now the mixture of the two salts softens, it is true, below 300°C . indeed a partial softening commences about 200°C ., but even at 240°C . this fusion is only semi-fusion. Incipient decomposition manifests itself in the semi-fused mixture, at about 230°C ., but the gas is only evolved at what I might term a moderate speed at 240°C . and at fair speed at 250°C . On lowering the temperature from this higher point gradually to 200°

at this temperature only a very faint and slight evolution of gas occurred, in fact, evolution was only just perceptible, and after a short time ceased. But 240° , the point at which the mixture shows but a reasonable speed of evolution of nitrous oxide, is one at which the nitrate of ammonium itself has overstepped its equilibrium of stability, and tended to violent evolution. Meantime it was ascertained that nitrate of ammonium begins to evolve nitrous oxide between 170° and 180° , and that the rapidity of evolution of the gas at 215° was fully as great as that from the mixture at 240° or 250° C. The trials were made in the paraffin bath in perfectly similar bulb tubes, and with thermometers in the bath and in the salts. Thus, to get the mixed salts so to mutually decompose as to yield nitrous oxide with reasonable rapidity it is necessary to acquire a temperature at which nitrate of ammonium cannot exist. There is a kind of critical point for ammonium nitrate, and that point is rough below 240° C.; it is even below 200° C. The way of representing the change which takes place on heating the mixture of equivalent weights of nitrate of sodium and sulphate of ammonium for the production of nitrous oxide, is to the best of my belief best represented as follows—

No doubt, when a portion of $(\text{NH}_4)_2\text{SO}_4$ is formed we have present the nascent elements of ammonia and nitric acid, but unite to form nitrate of ammonia at 240° or 250° C. they cannot. We have seen, moreover, that both NO and N_2O , by reducing agents form nitrous oxide, so that were these gases present momentarily in the passing reaction referred to, the change to the final nitrous oxide is perfectly natural and intelligible. This only indicates, I think, the ease and readiness with which the gaseous elements of nitrate of ammonium under a variety of conditions of temperature can adapt themselves in a variety of changes.

NITRATE OF LEAD AND SULPHATE OF AMMONIUM.—By heating nitrate of lead, PbN_2O_6 , alone we adopt the tolerably ancient and classical method for producing nitrogen peroxide, NO_2 , along with oxygen and oxide of lead. On heating a mixture of nitrate of lead with its equivalent of sulphate of ammonium, however, I find that instead of the red fumes of NO_2 the colourless gas N_2O is evolved. This experiment, along with that of heating lead nitrate alone, I would suggest as a pair of instructive lecture experiments to show side by side in illustration of the degree of stability or instability of the N_2O_3 molecule under the influence of heat, alone, and in presence of such a reducing agent as NH_3 .

SODIUM NITRATE AND AMMONIUM OXALATE.—This mixture did not yield nitrous oxide, the decomposition of the ammonium oxalate apparently occurring at a temperature below that at which the necessary decomposition of the sodium nitrate occurred. Such a result might be expected, since oxalic acid decomposes just above 160° .

SODIUM NITRATE AND AMMONIUM PHOSPHATE.—The dry mixture, on heating, evolves nitrous oxide, but not so effectively as the ammonium sulphate mixture.

BARIUM NITRATE AND AMMONIUM SULPHATE, also yield nitrous oxide on heating, but with much more difficulty than lead nitrate and ammonium sulphate.

I desire to express my best thanks to Messrs. S. Ernest Linder and H. Pietou, formerly students of University College, and especially to my late assistant, Mr. Hamilton, for their assistance in carrying out several of the details of this experimental inquiry with me.

I am continuing the investigation of this subject, and more particularly of the intermediate reactions, and hope shortly to publish more details.

SCHÜRMANN'S REACTIONS.

BY WATSON SMITH,

Lecturer in Chemical Technology in University College, London.

This paper deals with reactions which are the outcome of an investigation forming the subject of an Inaugural Dissertation conducted by Ernst Schürmann in the laboratory of Professor Lothar Meyer of Tübingen, the details appearing in Liebig's *Annalen*, **249—250**, 1888—89. 326—350.

For some time past in a somewhat desultory way I have been examining sundry of these reactions to see if any, and how many, are capable of any more practical application. In this inquiry I have been greatly aided by my late assistant Mr. Hamilton, as well as more recently by my present assistant Mr. J. C. Chorley. The original title of this investigation is, "Die Verwandtschaft der Schwermetalle zum Schwefel," and it seems that the first man who experimented as to the action of various solutions of metallic salts on the insoluble sulphides of the silver, copper, and iron groups, was E. F. Anthon in the year 1837, the results appearing in the *J. für prakt. Chemie*, **10**, 353. In this direction he investigated the metals Pb, Cd, Cu, Ag, Co, Ni, Mn, and Fe. He caused, for example, silver nitrate to react upon CuS, and realised the following equation:—

Thus he succeeded in arranging the metals referred to, in a series such that the salt of any one of these is capable of decomposing the sulphide of the metal following it, or the sulphide by the saline solution of the metal preceding it. His arrangement was Ag, Cu, Pb, Cd, Fe, Ni, Co, and Mn. Schürmann extended the investigation to the following metals, Sb, As, Pb, Cd, Fe, Co, Cu, Mn, Ni, Pd, Hg, Ag, Ti, Bi, Zn, and Sn.

As regards the salts used, the sulphates of Cu, Cd, Zn, Ni, Fe, and Mn, the nitrates of Pb, Co, Bi, Ag, and Ti, and the chlorides of Sn, Pd, and Hg, were used. Besides these, tartar emetic for Sb, and arsenious acid were employed.

In the experiments, so as to effect fairer comparison, equivalent weights of such salts, &c., were taken, as produced no precipitates in the solutions. One or two specially striking reactions are worthy of note in founding the table to be given. These are: (1.) That, between lead nitrate with two equivalents of sulphide of zinc, lead sulphide and zinc nitrate being very quickly formed, so that in less than two hours the whole of the lead will be in the precipitate and one equivalent of Zn in solution; also (2.) Those between arsenic trisulphide and tartar emetic, stannous chloride and zinc sulphate, which latter completely decompose the arsenic trisulphide.

I ought perhaps to mention that the sulphides experimented upon in this research were not natural sulphides, but sulphides obtained by precipitation. The total results are collected together in a table in which the salts marked with an *asterisk* only acted upon the adjacent sulphides in sealed tubes under pressure.

Sulphides.	Completely decomposed.	Partially decomposed.	Not decomposed.
Ag_2S	$\text{Hg(NO}_3)_2$..	CuSO_4
As_2S_3	HgCl_2 CuSO_4	FeSO_4	..
..	$\text{C}_6\text{H}_5\text{O}_2\text{SbK}^*$ $\text{Pb(NO}_3)_2^*$ ZnSO_4^* NiSO_4^*
Bi_2S_3	CuSO_4	..	CuSO_4 $\text{Pb(NO}_3)_2$ $\text{C}_6\text{H}_5\text{O}_2\text{SbK}$
CdS	CuSO_4	$[\text{SnCl}_2]$	$\text{Pb(CH}_3\text{COO)}_2$ ZnSO_4 NiSO_4 $\text{C}_6\text{H}_5\text{O}_2\text{SbK}$

Sulphides.	Completely decomposed.	Partially decomposed.	Not decomposed.
CoS.....	CuSO ₄ Pb(NO ₃) ₂	ZnSO ₄ NiSO ₄ FeSO ₄	MnSO ₄
CuS.....	HgCl ₂ AgNO ₃ PdCl ₂
FeS.....	ZnSO ₄ NiSO ₄ Co(NO ₃) ₂	TiNO ₃	MnSO ₄
HgS.....	PdCl ₂	..	CuSO ₄ AgNO ₃
MnS.....	NiSO ₄ Co(NO ₃) ₂ FeSO ₄ TiNO ₃

PdS.....	HgCl ₂ AgNO ₃
Sb ₂ S ₃	HgCl ₂ CuSO ₄	..	[CdSO ₄] SnCl ₂ ZnSO ₄
SuS.....	CuSO ₄ [CdSO ₄]	..	C ₂ H ₅ O ₂ SbK Pb(NO ₃) ₂ ZnSO ₄
Tl ₂ S.....	Pb(NO ₃) ₂ ZnSO ₄ NiSO ₄	FeSO ₄	..
ZnS.....	CuSO ₄ Pb(NO ₃) ₂ CdSO ₄ SnCl ₂	NiSO ₄) But little Co(NO ₃) ₂) action.	FeSO ₄ TiNO ₃

The conclusion drawn as to the affinity of the metals referred to for sulphur is that this affinity continually diminishes from palladium to manganese in the following series:—

Pd, Hg, Ag, Cu, Bi, Cd, Sb, Sn, Pb, Zn, Ni, Co, Fe.
106 209 198 63 208 112 122 118 207 65 59 59 56
As, Ti, and Mn.
75 204 55

The author endeavours to show how by means of the knowledge of relative affinities thus portrayed, certain useful results may be attained, for example, in separating a metal from a large excess of another metal, and even going a step farther than this by means of fractional precipitation with sulphuretted hydrogen. Take one case, 6.3 cc. HgCl₂ were mixed with 6.3 cc. CuSO₄, diluted to 50 cc., and when the solution was brought to boiling, 20 cc. of sulphuretted hydrogen solution were added. The solution was kept boiling for a quarter of an hour, and filtered. Mercury alone remained in the precipitate, and copper in solution.

In this way Schürmann completely separated from each other the following:—

Hg from Cd, Pb, Sb, and Ag.
Pd from Hg and Ag.
Cu from Sn and Cd.
Ag from Cu.

It was also shown that thus in neutral solution nickel is precipitated before cobalt.

Schürmann has lastly arranged the metals according to their greater or less affinity for sulphur in the *periodic system*, and he expresses, by the sign >, which of two

neighbouring elements has the greater inclination to form sulphides, thus:—

VII.	VIII.	I.	II.	III.	IV.	V.
Mn < Fe < Co < Ni < Cu > Zn > As						
55 56 59 59 63 65 75						
	Pd > Ag > Cd > .. Sn < Sb					
	106 108 112 118 122					
		Hg > Tl < Pb < Bi				
		200 204 207 208				

Regarding the elements belonging to each family alone, if his reasoning be correct, we see that those with the largest affinity for sulphur also possess the largest atomic weights. Group IV. forms an exception, for Sn is precipitated before Pb. A few other remarkable relationships are referred to, though to these several exceptions have to be added.

Now, with regard to my own experiments, these were, as I have already said, with the object of testing these reactions to some extent to discover if any of them were likely to be of industrial use, for I must add that several trials in the use of the list given only brought failures.

For industrial purposes I desired to experiment not upon precipitated sulphides alone, but upon mineral sulphides. One of the first of these I tried was *galena*. Looking at Schürmann's table, we see that copper nitrate is set down as a salt, the solution of which should effect a complete decomposition of lead sulphide. On sealing up a quantity of galena with a trifle less than its equivalent of copper acetate in a strong glass tube, and heating up to 130° C. for about a couple of days, the blue colour had quite disappeared. A black precipitate truly remained, but it was no longer one of lead sulphide but of cupric sulphide, whilst the solution was one of pure lead acetate, on evaporating which the beautiful specimen of pure lead acetate I now pass round was obtained. On exposing the precipitate in a damp state on the filter to the air, and occasionally moistening, and finally washing with a little hot water, this solution of copper sulphate was obtained.

Here is a possible useful application arising from a study of such reactions. Now, suppose silver was present in the galena, let us see what should happen. On referring to the table we observe that when using silver nitrate, silver appears to have a greater affinity for sulphur than copper has, and hence must remain as sulphide with the sulphide of copper, or if the sulphide of copper be oxidised to sulphate, the silver will remain in the residue.

The other double decompositions I have attempted and effected are as follows:—

In Aqueous Solution.	Results.
Copper sulphate with slight excess of CoS, heated 120° for 20 hours.	Complete decomposition.
Copper sulphate with slight excess of NiS, heated 130° for 4 days.	" "
Copper sulphate with slight excess of MnS, heated 130° for 6 days.	" "
Copper chloride with slight excess of As ₂ S ₃ , heated 120° for 20 hours.	" "
Lead chloride with slight excess of As ₂ S ₃ , heated 150° for 60 hours.	Partial decomposition.
Copper chloride with slight excess of Sb ₂ S ₃ , heated 130° for 4 days.	" "
Zinc chloride <i>in excess</i> , with As ₂ S ₃ , heated 115° and 165° for 25 hours.	Very little decomposition.
Antimony trichloride <i>in excess</i> , with dry As ₂ S ₃ , fused together at 170° for 3-4 days.	Little decomposition.

With the remark that an inspection of the tabulated reactions of Schürmann will show that copper as nitrate, chloride, or acetate furnishes at once the cheapest, the most far-reaching reagents (salts) of any; also with the suggestion that metallurgical chemists may yet find considerable value in Schürmann's table of double decompositions both analytically and industrially, I will conclude with a few critical remarks as to Schürmann's scientific attitude in viewing such reactions as these as due to the affinity of

the sulphur of the sulphides for the metals of the salts presented to them. Though I had in my experiments noted what Schürmann might have regarded as differences of affinity of the sulphur (*vide* my results as given where Pb, Cu, Zn, and Sb, as chlorides, though sufficiently far removed in Schürmann's list from the metals whose sulphides they are set to decompose, exert but little action), yet I had not at first the intention of applying any general criticism to Schürmann's standpoint, but of limiting myself to the bare experimental facts elicited for the sole purpose of application, technologically, to the treatment of mineral sulphides. My friend Dr. C. R. A. Wright, however, thinks the opportunity should not be lost of demonstrating a certain fundamental fallacy which lurks in Schürmann's generalisation, and which leads him to attempt definite scientific classification of the metals referred to. It was, perhaps, another thing had such classification been put forward as a rough technical guide with reference to the results of the special reactions examined, but I thoroughly agree with Dr. Wright that, since the attempt has gone further than this, correction should be applied. Dr. Alder Wright's views are as follows:—

The interesting cases of double decomposition between insoluble sulphides and soluble salts described by Schürmann are apparently due as much to the difference in affinity of the two metals present for the *acid radical of the soluble salt*, as to the difference in their affinities for sulphur; and hence the experiments hardly warrant any classification of metals based on their relative affinities for sulphur as thus deduced. For instance, when lead sulphide and copper nitrate solutions act on one another, copper sulphide and lead nitrate are formed; thus—

But it does not therefore follow that copper has a higher affinity for sulphur than lead; in point of fact the reverse is the case, for according to Julius Thomsen's thermochemical affinity values, the heat of formation of copper sulphide is *less* than of lead sulphide, *viz.* (using Thomsen's notation).

	Calories.
Pb, S.....	20,430
Cu, S.....	9,760
Difference.....	10,670

If therefore lead could react on copper sulphide at the ordinary temperature, it is to be expected that lead sulphide would be found and copper liberated; at any rate this change should be brought about more readily than the converse change, since the former would be accompanied by a considerable heat evolution (10,670 calories), and the latter would require an equal heat absorption.

The heat of formation of lead nitrate solution (from lead, oxygen, and dilute nitric acid) is considerably greater than the heat of formation of copper nitrate solution (from copper, oxygen, and dilute nitric acid); hence a Daniell cell may readily be obtained by placing lead in lead nitrate solution, and copper in copper nitrate solution,* the energy exhibited by the current being due to the displacement of copper from nitrate by lead, just as in the ordinary Daniell cell it is gained by the displacement of copper from sulphate by zinc. Thomson's values are—

	Calories.
Pb, O, 2 HNO ₃ aq.....	68,070
Cu, O, 2 HNO ₃ aq.....	52,410
Difference.....	15,660

Hence it results that when lead sulphide and copper nitrate solution act on one another producing copper sulphide and lead nitrate, the action as a whole is accompanied by heat evolution to the extent of 15,660—10,670 = 4,990 calories. Hence the reaction takes place, notwithstanding that the affinity of copper for sulphur is *less* than that of lead for sulphur.

* I have also used thin, clean sheet lead, and still better spongy lead, to precipitate small quantities of copper from solutions of ammonium acetate slightly acid with acetic acid.—W. S.

Since the heat of solutions of metallic oxides in dilute nitric, hydrochloric, sulphuric, or acetic acids, &c., in many cases differ but little, it follows that in such cases the difference in heat of formation of a given pair of salts containing different metals, but the same acid radical is practically the same as the difference between the heats of formation of the oxides of the two metals. Hence the question as to whether the sulphide of a metal A will or will not be decomposed by a soluble salt of another metal B, will in such cases depend on whether the sum of the heats of formation of the oxide of A, and the sulphide of B is or is not greater than the corresponding sum in the case of the oxide of B and sulphide of A.

DISCUSSION.

The CHAIRMAN said that, for himself, he was not quite convinced by the argument used as to the course of the reaction with the sodium nitrate and ammonium sulphate. It seemed to him that the argument from temperature still left it ambiguous as to whether nitrate of ammonium was not formed and immediately decomposed, the fact that it could not exist at such temperatures being no argument to that end. He had nevertheless a strong suspicion about these reactions that were said to occur in two stages. He had always held the opinion that they were simultaneous.

Mr. OSCAR GUTTMANN said that it might be of interest to hear, in addition to Professor Watson Smith's highly interesting experiments, that a friend of his had prepared nitrate of ammonium by mixing solutions of nitrate of soda and sulphate of ammonium, and exposing the mixture to a temperature of -15°C . He had seen a sample of this nitrate of ammonium, about a year ago, after it had been lying open on a writing table for several days. He saw the same sample again about four weeks ago, and it was upon both occasions perfectly dry. His friend preferred this way of making nitrate of ammonium to that of absorbing ammonia gas by nitric acid, as he thereby avoided the impurities contained in the nitrate of soda; and it was to these impurities that he attributed the hygroscopic qualities of nitrate of ammonia, whilst the sample mentioned above was evidently free from that defect. There was still some doubt whether this process could be worked on a large scale, as the investigations were not yet completed.

Mr. C. F. CROSS remarked that the author had omitted mention of Ackworth and Armstrong's researches on the reduction of nitric acid by metals (Chem. Soc. J. 1877, 32, 54—90), in which these authors showed that nitrous oxide was formed to the extent of from 1 to 85 per cent. of the total gaseous products ($\text{NO}, \text{N}_2\text{O}, \text{N}$) according to the conditions of the action.

The equation proposed to account for the production of N_2O under the conditions described in the paper did not attempt any explanation of the reaction. It appeared probable that in the molecular re-arrangement which took place ammonia was oxidised to hydroxylamine concurrently with the reduction of the nitric to the nitrous group, and it might be possible to prove the occurrence of this reaction as the intermediate stage of the decomposition. Hydroxylamine salts and nitrites reacted quantitatively in aqueous solution according to the equation—

and the decomposition appeared to be realisable under a wide range of conditions.

Mr. CRESSWELL asked whether anything had been done with Schürmann's reactions in respect of the two metals, magnesium and aluminium, the symbols of which he did not see on the board. The main reaction of the Schaffner and Helbig process depended entirely upon the want of affinity of magnesium for sulphur. A patent had recently been taken out—or rather an investigation had taken place—as to the possibility of manufacturing aluminium from aluminium sulphide because of the amenity of that body to treatment by electrolysis.

MR. WATSON SMITH, in reply to the observations made about the nitrous oxide process, said that it appeared to him to be a matter of logic,—that if only partial fusion, amounting to mere softening, could take place at certain temperatures very high up in the scale, and if no proper fusion took place, then there was no real chemical contact. He could not understand in such a case that a chemical change would entirely occur: it might, however, do so to a certain extent. It appeared to him to be an extremely interesting thing that the aqueous solution of these two salts should decompose at the low temperature referred to. From the dry mixture at 240° nitrous oxide came off somewhat slowly; but if nitrate of ammonia were there it would come off vigorously, tending to explosion. But that was not the case. In point of fact, if nitrate of ammonium were heated by itself at 215°, the evolution was as rapid as from the mixture heated to 240°. With regard to the hydroxylamine reaction suggested by Mr. Cross, he did not think that hydroxylamine itself would resist that temperature. If these things did not exist at the temperature given, he could not see that such a change would take place as one could reasonably show by an equation. It would certainly be a mixture of the elements of the substance; but he did not regard that as the substance itself, especially when one considered Berthelot's investigations on the seven different reactions possible on heating nitrate of ammonium. Referring to Mr. Cresswell's question, he believed that Schürmann had omitted aluminium and magnesium because they did not form sulphides under the same conditions as the other metals which he had included.

The results are as follow:—

JUTE.						
	I.		II.		Mean.	
Carbon	46.18		45.12		45.65	
Hydrogen	5.83		6.33		6.08	
Oxygen	47.99		48.27		48.27	

COTTON-WOOL.						
	A. and C.			B.		
	I.	II.	Mean.	I.	II.	Mean.
Carbon	42.66	42.16	42.41	42.93	42.47	42.70
Hydrogen	6.25	6.16	6.20	6.33	6.07	6.20
Oxygen	51.09	51.68	51.39	50.74	51.56	51.10

The jute contained 11.35 per cent. of moisture; samples A and C, 5.34; and sample B, 5.83 per cent. The moisture was estimated by drying over sulphuric acid for four weeks in a vacuum.

Although these bodies cannot be regarded as pure chemical individuals, it is interesting to compare the results of certain definite compounds with the results of their analysis. Those which most nearly approach the above composition are:—

	C.	H.	O.
Pentosane or xylene ($C_5H_8O_4$) ¹⁰	45.45	6.06	48.48
Cellulose ($C_6H_{10}O_5$)	44.44	6.17	49.38
Grape-sugar, $C_6H_{12}O_6$	40.00	6.66	53.33
Starch (probably) $C_6H_{10}O_5$	43.63	6.26	50.10

These samples were distilled in the manner described in our first paper (this Journal, 1892, p. 395). As before, the gas was collected and analysed; and the distillate was separated into three portions, viz., weak acetic acid, crude methyl alcohol and tar.

The results are as follow:—

THE DESTRUCTIVE DISTILLATION OF WOOD.

BY JNO. C. CHORLEY AND WM. RAMSAY, PH.D., F.R.S.

LAST May we brought before the Society the results of some experiments on the distillation of wood. We have followed up these researches by investigating the behaviour of compounds which have a greater claim to be considered definite. These are jute and cotton-wool.

The sample of jute was purified by boiling it in a dilute solution of caustic soda; the cotton-wool was of two qualities; the samples A and C consisted of crude wadding, while the sample B was purified wool, and is sold under the name of medicated cotton.

These substances were analysed without having been dried; they were afterwards dried and the analyses calculated on the dry material.

	Jute.				Cotton-Wool.		
	I.	II.	AI.	A2.	B1.	B2.	C.
Weight in grams	71	73	45	60	67	45	50
Charcoal, per cent.	28.71	32.87	33.33	30.00	34.33	3.44	33.00
Distillate	57.70	43.15	53.33	50.00	43.32	51.11	46.00
Carbon dioxide	Lost	12.33	6.66	9.53	5.22	7.77	11.00
Other gases	11.45	6.68	10.47	17.13	6.68	10.00
Vol. of gas, cc.	3,000	2,500	2,000	2,700	1,500	1,000	3,500
Vol. of gas from 100 grams	4,220	3,420	4,000	4,500	2,240	2,200	7,000
Composition of gas per cent.:							
Carbon monoxide	78.80	85.29	76.92	85.74	54.14	52.46	76.20
Oxygen	3.01	1.73	3.06	2.80	8.50	4.73	3.34
Residual gas	18.19	12.95	19.12	11.46	37.36	43.11	20.46
Tar, per cent.	14.78	6.85	..	8.33	9.70	13.33	12.00
Acetic acid	0.10	1.40	..	2.44	1.75	2.11	1.31
Methyl spirit	10.08	3.94	10.24	7.07

In contrasting these numbers with those obtained in distilling wood, it is to be remarked that the percentage of charcoal is considerably smaller than with such fibres; that of distillate smaller, and that of carbon dioxide larger than with wood. The acetic acid is very much less; and that of the impure mixture counted as methyl-spirit is particularly high, in almost every case.

In comparing jute with cotton wadding and with cotton wool, it appears that the chief difference between them lies in the amount of carbon monoxide which they yield. While jute and impure cotton wool give a gas containing as much

as 70 to 80 per cent. of this constituent, the pure cotton wool yields only a little over 50 per cent., the nitrogen and residual gas being correspondingly increased. We do not think that all of this increase can be accounted for by ascribing it to air present in the retort, though there is no doubt that some may thus be accounted for.

We next pass to the thermal behaviour of the fibres.

The best idea of the changes of temperature distillation is gained by a graphic representation of the temperatures of the bath, contrasted with those of the substance being distilled, time being taken as ordinates.

We give tables, however, showing the actual temperatures in the air-bath (outside temperatures), and of the fibre (inside temperatures), at different intervals of time during distillation, for crude cotton-wool, and for jute; the curves are a graphic representation of these numbers.

Cotton-wool.			Jute.		
Time.	Outside.	Inside.	Time.	Outside.	Inside.
10.50	250	100	11.15	100	63
55	270	115	30	200	63
11.00	285	150	45	255	80
05	295	190	12.00	278	150
20	323	275	05	292	240
25	324	295	10	302	249
30	324	310	15	312	295
35	324	323	17	317	328
49	325	340	18	321	375
43	325	348	19	323	372
45	324	345	20	323	365
50	322	333	25	322	340
55	320	326	1.00	317	320
12.00	319	322
05	319	319
1.45	325	324

With cotton-wool the temperatures are practically equal at 11.35. Eight minutes later the wool is 13° higher than the bath. In 17 minutes the temperatures are again practically equal. The whole rise and fall took place in 25 minutes.

With jute the temperatures may be considered equal at 12.16; at 12.18, the jute had a temperature no less than 54° higher than that of the bath; but the fall of temperature in this case was much more gradual; it was not until 1.00 that the temperatures were practically equalised

Hence the rise is a very sudden one, occupying only two minutes, and I think that it will be allowed that this approximates to an explosion. Gas was evolved with great rapidity during this sudden rise of temperature, and it is perfectly evident that the exothermic reaction is a violent one.

With purified cotton-wool, there were no signs of an exothermic reaction. The whole operation appeared to be of the nature of an ordinary distillation.

The conclusion is therefore forced upon us that the substance which decomposes in this manner is not cellulose, but some substance which may be removed from woody fibre by solvents. It appears not to be the same substance as the one which yields acetic acid on distillation, for jute, which decomposes with such sudden evolution of heat, gives a minimum percentage of acid. Nor does it appear to accompany the mixture reckoned as methyl spirit in our table, for both jute and pure cotton-wool yield this distillate in considerable quantity.

Oak and beech wood therefore must contain some substances which yield acetic acid on distillation, and which is not (at least not wholly) the cause of the exothermic reaction which accompanies their decomposition. That substance has been removed in the purified wool, which yields a minimum quantity of acid; and with it the body which causes the exothermic reaction has also been removed.

The direction of further research is obvious; but circumstances have prevented the authors of this paper from continuing the investigation; moreover, the problem is in the hands of others. Messrs. Cross and Bevan are working with matters extracted from wood fibre by solvents, and Herrn Flint and Tollens are engaged in determining the nature of the decomposition products of fibre (Berichte, 1892, 2316). From the labours of these chemists we may hope soon to obtain a satisfactory idea of the real constitution of different varieties of woods; and we are content to leave the subject in such competent hands, resting satisfied that if our experiments have contributed even a little towards the solution of such a complicated problem.

Only two points remain for mention. One is the striking circumstance that the percentage composition of xylene and jute are the same, viz., $(C_8H_8O_4)_n$. The other is the fact that products removed from cotton-wool during its purification appear to be the cause of the large amount of carbonic oxide in the gases evolved. For, while jute and impure cotton-wool yield amounts of gas varying from 3,420 to

7,000 cc. per 100 grms., purified wool yields only 2,200 cc. Moreover, the former yields gases consisting mainly of carbonic oxide (76 to 85 per cent.), while the gases from the latter contain little over 50 per cent. It is possible that some clue may be given by these observations to the particular mode of decomposition of the chemical constituents of the fibre.

DISCUSSION.

Mr. A. H. MAYSON wished to know whether the medicated cotton was pure cotton, as the substance was sometimes rendered impure in the process of manufacture by other combinations.

Mr. C. F. CROSS said that he had been engaged on this subject some years, and knowing that it was to fall into his hands, he had been fortunate in obtaining a gentleman to undertake the prosecution of this question of determining the reactionary agents, and also the variations in the products themselves. As they had been asked to place the subject before the Society at an early date they would endeavour to do so.

Professor RAMSAY said that he believed that what was known as medicated wool was practically pure cellulose, being cotton wool denuded of soda, acetic acid, &c.

Professor FOSTER said it was quite possible to get pure cellulose in the form of cotton wool. He had been surprised at its purity, for it burned clean away and left no acid residue.

The CHAIRMAN said that it was a matter of regret that Professor Ramsay and Mr. Chorley's paper was in a certain sense the final paper on the subject. While he was very glad to hear that Messrs. Cross and Bevan promised a contribution on the same subject, it did seem a pity that Professor Ramsay should drop it, as it seemed to him to provide an ample field for both, from which useful results might have been expected.

MR. HENRY BRUNNER IN THE CHAIR.

CHAIRMAN'S ADDRESS ON ARTIFICIAL MANURES FOR FRUIT CULTURE.

(ABSTRACT.)

THE subject of fruit-growing for profit is one that has during the last few years had increasing attention drawn to it, partly owing to the hope that it may prove a means of bettering the condition of the land cultivator, and partly due to the growing demand for fruit as an article of food. From figures kindly supplied by Sir James Whitehead, Master of the Fruiterers' Company of London, it appears that the total area devoted to fruit culture in this country in 1891 was 268,700 acres. This would represent a value of 9,000,000*l.*, taking 30*l.* per acre as a low average value of the produce. In fruit-growing it may be taken that, roughly, one-fourth of the cost of production is due to the necessary supply of manure, and therefore it is evident that if a large proportion of the natural manure used be replaced by chemical manures, a considerable benefit to the chemical industry of the country will accrue. It appears that to-day the balance of opinion is against the total replacement of natural manures by artificial, but there is no doubt that a large proportion may be so substituted with advantage to the crop and with economy to the cultivator. The author's own experiments made with strawberries show that by employing chemical manures far less potash, phosphoric acid, and nitrogen is required per acre than is the case with ordinary farmyard manure, as owing to their soluble form they penetrate the soil more rapidly and deeply.

The requirement of an acre of land planted with apple trees would amount to about 20 tons of farmyard manure once in three years, whilst the necessary ingredients contained therein would be supplied by the yearly use of 500 lb. of kainit (at 13.5 per cent. K_2O), 120 lb. of superphosphate (at 16 per cent. soluble P_2O_5), and 360 lb. nitrate of soda, or a total for the three years of 26 cwt. of material. From the above it is evident that in certainty of effect, in convenience of handling, and in distribution over the soil, chemical manures possess distinct advantages. The author does not recommend the complete discarding of farmyard manures, but rather the adoption of some system of rotation of manures such as that recommended by Wagner of Darmstadt for the cultivation of vines, in which farmyard manure is supplied in the first year and supplemented by chemical manures only in the second, third, and fourth years. It has been urged against chemical manures that they render the soil poorer in organic matter, whilst farmyard manure has the reverse effect, but it has been shown by Joulie that the more abundant harvests produced by the use of chemical manures leave a larger proportion of residues in roots and otherwise in the soil, and consequently that there is no impoverishment, but an increase in the quantity of organic matter in the soil.* By the use of chemical manures each ingredient can be adjusted to the requirements of the crops, which is obviously not the case with natural manures, whilst Ville has shown that more than one-third of the nitrogen contained in the latter is lost to the soil on account of the decomposition which the manure must first undergo before it can exercise its action.† The cost of carriage is also favourable to the employment of chemical manures. Superphosphate is the most suitable form of phosphoric acid for the fruit-grower, and it has the further advantage of supplying a considerable quantity of a soluble lime salt necessary for the building

* *Mercurie Scientifique*, Supplément du *Moniteur Scientifique* June 1892.

† Ville on "Artificial Manures," trans. by W. Crookes, p. 105.

up of healthy trees. Finely-ground basic slag is also likely to prove of great value since it contains 18 per cent. of phosphoric acid combined with lime in a fairly soluble form. The latter should be applied in larger proportionate quantity than the former, and will be found specially useful in preparing the ground before planting young fruit trees. Kainit affords the cheapest form of easily soluble potash, but contains only 13 per cent. of potash and as much as 40 per cent. of sodium chloride. The composition of the soil and the requirements of the crops must, to a large extent, determine the best form of potash salt to employ.

Taking into consideration their relative price, one of the following will be found most useful:—

(1.) "Pure sulphate of potash, magnesia, calcined. Guaranteed minimum 48 per cent. sulphate of potash, maximum, $2\frac{1}{2}$ per cent. chlorine." It contains usually about—

	Per Cent.
K ₂ SO ₄	50
MgSO ₄	41
NaCl.....	3

(2.) "Ground calcined manure salts. Guaranteed minimum 31.5 per cent. potash," containing usually—

	Per Cent.
KCl.....	51
MgSO ₄	17
MgCl ₂	7
NaCl.....	14

It must be borne in mind that potassium chloride tends to decrease the calcium carbonate of the soil. Nitrate of soda is the best and most economical nitrogen manure for fruit cultivation; sulphate of ammonia is less suitable.

SESSION 1892.

Friday, 2nd December.—Dr. Carl Otto Weber. "Cop Dyeing."

Meeting held Friday, 4th November 1892.

MR. I. LEVINSTEIN IN THE CHAIR.

CHAIRMAN'S ADDRESS.

ADDRESS DELIVERED AT THE OPENING OF THE SESSION (NOVEMBER 1892) OF THE MANCHESTER SECTION OF THE SOCIETY OF CHEMICAL INDUSTRY.

TEN years have now elapsed since the establishment of the Manchester Section of the Society of Chemical Industry,

and the results achieved have fully justified its formation. Many interesting papers have been brought before us, and their number, as well as the number of our members, has been steadily increasing; it has, moreover, brought together and united in intimate association those engaged and interested in the development of our industries. To the action of this Section is due the fact that we are now represented in the Manchester Chamber of Commerce, an association which, until this took place, had been almost exclusively occupied in the consideration of questions relating to the cotton industry; the formation of the Chemical Section in the Chamber was the means of breaking down this barrier of exclusiveness, and extending the scope of its usefulness. That the principle of forming special sections for special trades or industries was a sound one is clear from the fact that the example set by the establishment of the Chemical Section has been followed by other trades. That section, although comparatively young, has already had to deal with a number of subjects which concern our industries, such, for instance, as the French and Spanish Tariffs; Patent Laws; Smoke Nuisance; Building Bye-Laws; Weights and Measures Act; Stills in Chemical Works, &c. Some time ago you referred to that section certain clauses of the Building Bye-Laws of the Manchester Corporation which you considered as injuriously affecting our industries, and, as you have already heard from the letter read by our secretary, bye-law 31, the building committee of the Corporation has promised the Council to recommend the amendment of this bye-law in accordance with your representations and suggestions. As far back as 1890 that section furnished the Board of Directors with a report on patent law amendment, as far as the regulations of those laws concerned our industries; this report has been approved by our Society, and support has been promised by other Chambers of Commerce. After repeated discussions it has, however, been thought that the question of further amendment is one which naturally concerns the interests of all trades and industries, and that any representations with regard to such amendment should be on broader lines and not confined to one particular industry, and for this reason the Board of Directors has recently decided to form a special committee, consisting of the chairmen of the various sections, with power to add to their number, for the purpose of devoting its attention in the first instance to the consideration of the advisability of amendment, and if necessary to the eventual recommendation of such steps as may be thought requisite. That there is really need for amendment will scarcely be disputed by those who have any acquaintance with the subject; difference of opinion may, however, exist as to what reforms should be made. The Patent Law Reform Association in Liverpool, for instance, is agitating for the substitution *en bloc* of the American patent system; how far such a proposition is wise I am not prepared to say, but one thing appears to me of paramount importance, and that is a painstaking examination of the subject-matter and of the specification of every patent before it is granted, as is the case in America and Germany. Such an examination would at once protect genuine and honest inventors, and by giving a valuable title benefit both them and our trades and industries, and would remove the large number of bogus and "bluff" patents now in existence taken out by unscrupulous patentees for the sole purpose of blocking *bonâ fide* inventions, thereby interfering with the legitimate development of our industries. As far as chemical patents are concerned, I hope that this committee will recommend the suggestion also made in the report furnished to the Board by the Chemical Section, viz., the necessity of distinguishing, in the application of the law, between chemical and mechanical patents. The present and past years have been productive in the passing of certain Acts more or less concerning our industries, such as the Building Bye-Laws; Weights and Measures; Extension of the Alkali Act (Noxious Trades); Smoke Prevention; Rivers Pollution, &c.; all enacted for the protection of common interests, and I believe that I am only expressing the views held by the majority of our members in stating that we by no means look upon the establishment of these Acts with any dislike; on the contrary, most of us have by

now found out that the enforcement of some of them, if carried out with discrimination by competent and experienced men, may be of great advantage. Take, for instance, the old Alkali Act; this Act has been and still is a blessing to manufacturers, its enforcement being in the hands of accomplished and properly qualified experts, whose advice and suggestions have been of the greatest benefit to manufacturers, and moreover, in no instance have those gentlemen lodged a complaint without at the same time suggesting practical means for avoiding and preventing the alleged nuisance, and if all these Acts are only carried out in a similar spirit and by men at once competent and experienced, I have no hesitation in saying that we shall give them a hearty welcome. No chemical manufacturer endowed with ordinary common sense is desirous of creating a nuisance; more than this, he is thankful to those who can point out to him a way by which he may prevent the emission or discharge of matters which are almost invariably of value to him. On the other hand, no Act for suppression, mitigation, or prevention of any alleged evil arising from the carrying on of trades and industries can be enforced without serious injury to them, unless practical means are available for such prevention. If I may be allowed to advise our trades on this point, I would suggest that we use our utmost endeavours to prevent, as far as is practically possible, the discharge of any thing that is hurtful or annoying to others; that we consult and discuss together and advise each other with regard not only to any grievance under which we may be labouring, but also to the method and means for its removal, and for that purpose there is no better opportunity than those provided by the meetings of this Section. On the other hand, I trust that the authorities in whose hands lies the enforcement of these various Acts will remember the words of Professor Huxley, uttered before a large audience some years ago in the Town Hall when the question of technical education was coming to the front:—"We are at present in the swim of one of those vast movements in which, with a population far in excess of that we can feed, we are saved from a catastrophe through the impossibility of feeding them solely by our possession of a fair share of the markets of the world; and in order that that fair share may be retained, it is absolutely necessary that we should be able to produce commodities which we can exchange with food-growing people, and which they will take rather than those of our rivals on the ground of their greater cheapness or their greater excellence." These words struck me at the time as an admirable description of our present position and of what our aims ought to be in the effort to retain it. Manchester and its trade and commerce depend upon its industries, and its present and future prosperity depend upon their extension and development. Now one of the Acts, the Rivers Pollutions Act, does not quite as much concern ourselves, and as long as sewage is discharged into our rivers and their tributaries, the liquid discharges from chemical works will, if anything, in some instances lessen the evils caused by sewage pollution, but the purification of this sewage has afforded some of our members an opportunity of showing what can be done by chemical means to effect that object. A number of interesting papers and discussions have been before us during the past session, by which the fact was established that if iron salts are added in sufficient quantity and time be allowed for settling, an effluent is produced of sufficient purity to allow of its discharge into any river. The use of iron in one form or another is by no means new, but the difficulty which is involved in this question is one not only of efficiency, but also of economy, and this latter is now in a fair way of being overcome. We have in our immediate neighbourhood a number of works in which iron, in some form or another, and also the acids necessary for its conversion into the requisite soluble salts, are obtained as waste products, and for the utilisation of these waste products a number of patents have been taken out, and I hope that the outcome may be helpful in solving a problem which has puzzled many corporations and rural authorities.

Now, gentlemen, taking a general and brief review of the position of our trades, I regret to say that, with but few exceptions, manufacturers will have a hard struggle to

maintain their position and to make their business pay. Outsiders generally think that anything chemical means piling up money, but this is a complete fallacy. Our industries are not in a flourishing condition, and more than this, our prospects are in no way encouraging, and if, with the disadvantages under which we are at present labouring, any undue pressure or harassing policy is adopted, the consequences will be keenly felt.

There exist in our immediate neighbourhood many branches of these industries, and if none of these individually is so important as the cotton industry, yet taken together they find employment for a large number of hands and contribute considerably to the maintenance of the commercial greatness of our city. Some of our traders and manufacturers have been adversely affected by the great fall in the values of half-manufactured articles obtained from the by-products of gasworks; 90 per cent. benzol, for example, which last year was quoted at 3s. 6d. and 3s. 9d. per gallon, is worth to-day only about 1s. 5d., and there is every likelihood not only that this low figure may be maintained for some time, but that prices may fall even lower. We had, until lately, the poor consolation, so far as the coal-tar colour industry was concerned, of knowing that if Germany had outstripped us in the production of coal-tar colours, we at least held the key of the situation in supplying the principal raw materials, such as benzol, toluol, carbolic acid, ammonia, &c., but those days are now gone by. As a consequence of further improvements in the recovery of these materials from the gases of combustion produced in the conversion of coal into coke, Germany is now already in a position to obtain these articles as a by-product in quantities almost sufficient to meet her own requirements; and with a more extended application of the improved process to the coke ovens, she will be able to supply the whole of the benzol required at a much lower price than tar distillers and carbonisers could accept at the present market price for the crude material, and thus we shall most likely lose an important article of export. The consequences of this improvement will also be seriously felt by our corporation and the rate-paying community; considerably lower prices will have to be accepted by the gasworks for their tar and ammonia waters, and there appears little chance now of a reduction in the price of gas for manufacturing and lighting purposes, for not only has attention been directed to the regeneration of benzol, but considerable quantities of ammonia are also being obtained as by-products from the same source; indeed the consequence has already been that some of our carbonising works have had to suspend operations. It is, however, not only the coal-tar industry which has recently received a severe shock, but it may be said, without fear of contradiction, that the whole of the chemical industries of this country are in a certain state of stagnation; their progress and development are undoubtedly most unsatisfactory when compared with those of our great rival, and this state of things is perhaps not altogether confined to chemicals but extends also to other articles of manufacture. Who would ever have thought, say 20 years ago, that we were going to import cotton goods, or cotton machinery, or perhaps still less alkalis? At that time anything appertaining to cotton was of English origin; when we spoke of an alkali industry we had only England in our minds; and even then, though Germany was already making rapid progress in wresting from us a large portion of the coal-tar industry, she at least had then to depend to a large extent on us for the supply, not only of benzol and other crude tar products, but also for the alkalis required in the production of colouring matters. To-day the unexpected has become a fact; we are importing some kinds of cotton goods and certain cotton machinery, and we are importing alkalis; it is true the quantities are not as yet large, but who shall say that they may not rapidly increase, and that before we are fully aware of the fact? I cannot give a better example of the unsatisfactory progress of our industries than by selecting an article of very large consumption which enters into use in multitudes of branches of industry, and which may be taken as a fair test of the expansion or otherwise of other industries. I will refer you to a few comparative figures relating to the export of alkali.

EXPORTS OF ALKALI FROM ENGLAND TO GERMANY.

1881.	1891.
Cwt. 928,900	Cwt. 143,700

EXPORTS OF ALKALI FROM GERMANY.

1884.	For the half-year ended 30th June 1892.
Cwt. 351,402	Cwt. 433,824

without including potash. Assuming that Germany will export only a like quantity in the current half-year, we find that she has increased her exports, within a period of eight years, from 351,402 to 433,824 cwt., an increase of more than 20 per cent. Now, looking at the exports of alkalis from this country to all countries, say in 1883, and comparing the figures with those for 1891, we shall see that our total exports of alkalis, instead of having increased, have decreased by more than 10 per cent. during a similar period of eight years.

EXPORTS OF ALKALI.

1883.	1891.
Cwt. 6,947,000	Cwt. 6,225,953

These figures do not require elaborating, they tell their own tale; the only redeeming feature in this case is that the decrease is due not so much to inferior skill on our part as to the want of foresight on the part of our manufacturers, who would stick to antiquated processes, trusting to combinations and artificial raising of prices, which, as experience has taught us over and over again, could only result, as they have resulted, in failure. The high prices ruling for alkali during the last few years have not only reduced our exports of the article, but also injuriously affected other trades, especially those of paper-makers, dyers, calico-printers, bleachers, soap-makers, and chemical manufacturers, and with the small margins at which these trades are and have been working of late they can ill afford to pay more for an article largely used in their respective trades than is paid by other countries with which they have to compete in the world's market. New works have been started during the present year for the manufacture of ammonia-soda, and another new undertaking is shortly to commence operations, and it may be assumed that the price for this important article will by and by be reduced to a figure which will leave a fair working margin to the manufacturer, and compensate him for the difference in price by an increased consumption. Gentlemen, German producers can purchase to-day some of the principal raw materials, such as alkalis, sulphuric acid, benzol, and other products, at prices at least as low as those we have to pay; we have, therefore, in the future to reckon with a new factor, and one that may have a material and important bearing on the development of our industries. The battle for supremacy will have to be fought henceforth with equal arms, and with no advantage, such as we formerly had, on our side, and the victory will rest with the nation that turns to best account the materials at its disposal. Our whole aim must therefore be to concentrate our thought, skill, and energy on the conversion of crude and half-finished materials into products of the highest excellence and perfection, and in order to do so, we must give to the people in this country similar, or even greater facilities for acquiring the requisite scientific and technical knowledge as are enjoyed by our rivals. As one for some years

connected with the former management of the Manchester Technical School, I have regarded with great satisfaction the acquisition of this school by our corporation, and under the guidance of the able and energetic chairman of the Technical Instruction Committee, seconded by the eminent services of my friend, Mr. J. H. Reynolds, its director, it may be expected that we shall, before long, possess a technical school worthy of this great centre of industry, affording opportunities for acquiring technical knowledge as good as, or better than those at the command of the people with whom we have to compete. A special feature in the new school will be the silk-spinning, weaving, dyeing, and finishing department, and the school for bleaching, dyeing, printing, and finishing of all kinds of fabrics. So far, the teaching of the tinctorial arts, especially the application of chemistry to colouring fibres, has in all our colleges and schools been only very partially successful. No doubt students, on leaving, possess a fair amount of knowledge, but of a kind a great deal of which is never required in practice, and much that is required they have never been taught. The reason for such a failure is very evident. Success in dyeing, printing, and the accessory arts does not depend solely upon a sound knowledge of chemistry, but to a large extent, just the same as applied chemistry in general, upon chemical engineering. Hitherto, however, the student, after having gone through a science, and a so-called experimental course, in which no opportunity is afforded of becoming acquainted with the engineering part of his profession—his experience principally extending to the handling of beakers, glass cylinders, china basins, a few grains or grammes of drugs and colouring matters, and correspondingly small quantities of yarn or cloth—has found himself, on entering a dye or print works, in a similar position to a cow before a turnstile, not knowing where to turn or how to move: he feels that every ordinary workman in the place knows more about the complicated machinery and other appliances before him than he does. The consequence is that the foreman or manager looks over his shoulder, and the principal soon gets disgusted with his new acquisition from which he had been promising himself so much, and puts him down as a noodle only fit for testing a few drugs and nothing else, and in this opinion he shortly after becomes fully confirmed. Work is going wrong, goods are being spoiled, they are either spotted, or streaky, or "off shade," or have other possible defects attached to them. For the time the foreman is puzzled, he cannot account for the defect, and now here presents itself a glorious opportunity for our friend from the technical school or college. The principal consults him, and requests his advice as to how to get over the difficulty. The fact however, is, that in ninety out of a hundred cases this scholar makes a fool of himself, and ultimately the comparatively ignorant foreman solves the problem, and our student, carefully trained at the college, is sent back to the laboratory, apparently the only suitable place for him. Now, what is the cause of this, and how can such an ignominious failure be avoided? The reason is that the student has never, during the whole course of his training, met with any such or similar problems, and to solve these when met with one must possess, in addition to scientific knowledge, a thorough knowledge of the entire plant and machinery of a dye or print works, as the causes of these difficulties are frequently of a purely technical character, or of a chemical and technical nature combined. If, therefore, we want to train in our schools day-students destined to become foremen, or managers, or masters of such works, we must teach them the application of science to these industries with the appliances and apparatus which they will actually meet with in practice. We must have the school workshops equipped with the very latest and most modern machinery of this or any other country, which must be kept on a level with the progress of discovery and invention; we must have a model bleach, dye, print, and finishing works, of course on a small scale—but yet large enough to allow the yarns in our spinning department to be made up, bleached, prepared, dyed, &c., and the cloth woven in our weaving school to be bleached, printed, and finished; and the work turned

out must not be schoolboys' work, but equal to the best to be found in the trade. Only thus shall we be able to put our students in a position at once to confront and solve all the difficulties and problems which he may encounter in practice, and only thus will his scientific knowledge be of real advantage to himself and the trade. Such a student will at once command a higher salary, for he will, frequently from the very commencement, be in a position to point out to his employers any likely improvement, because his knowledge of a varied class of appliances may often be superior to theirs. A number of men thus trained will soon produce a marked effect on the goods turned out in our dye, print, and a finishing works.

That this view is practical one, is proved by the Dyeing School at Crefeld—the only school, in my opinion, worthy of the name—which has produced results so highly appreciated by the community and the trade generally, that the municipal authorities, supported by the Government, have resolved to remove the already large dyeing department from the school, and to erect a special building to carry out the work on a still more extended scale.

We are exporting annually more than twenty millions' worth of dyed and printed cotton goods, the largest portion of which comes from Lancashire; improved methods for cheaper production, and still greater excellence would, we may fairly take it, materially increase our exports of these goods, and find increased employment for our working classes, and towards accomplishing this important object such a school would render invaluable assistance.

DISCUSSION.

M. CRIPPIN said he felt very keenly the remarks made by the Chairman upon the Patent Laws, inasmuch as he had a patent which, had it not been that he had means wherewith to fight, would probably have never come to the front. He hoped that the Chairman as a member of the Chamber of Commerce would obtain its influence in securing Government protection, and reducing the Patent Law fees as in America and Germany. With regard to technical education, while he did not wish to discourage the Chairman and those associated with him in their endeavours to bring about a better state of efficiency, still he thought that the laboratory work done in the technical schools of this country was not brought to a practical issue. Unfortunately the men who worked by rule of thumb knew a great deal more than the student who had passed through a course of study at these schools, and this was mainly due to the deficiency of the teaching staff, and pupils not being in touch with practical work, as was the case in Germany.

Dr. HEWITT said he appreciated most strongly the Chairman's remarks on technical education, and he enforced them all the more, inasmuch as the previous speaker appeared not to fully comprehend them. The Chairman had pointed out the defects of the British system of technical training, and called attention to the fact that most students were quite unfit to guide men who had had a life-long experience, and who had acquired a certain amount of practical knowledge by observation. What was required was a system of technical education which would give students an opportunity of seeing a piece of cloth pass through the various processes of spinning, weaving, dyeing, and finishing, and of learning something with regard to the laws of motion and physics.

Students were admitted into technical schools without their having first of all received a preparatory training, and regardless of their fitness to take up any particular class of work; and another defect was mainly due to the common notion that a student after three years' experience at Owens College was competent to undertake practical work. Under these conditions the great wonder was that British manufacturers had maintained their supremacy as long as they had, and the only reason he could assign for it was the abundance and cheapness of coal and iron. What was required in England was something between the elementary school and the university, and the university and the works. With regard to the Rivers Pollution Act, he hoped the chemical manufacturers in that district would not depend upon the sort of defence set forth in the Chairman's address. He should be sorry to think that it could be argued that two

blacks made one white, and that because towns sent sewage into the streams and rivers chemical manufacturers ought not to do their utmost to prevent pollution. With reference to the alkali trade, he did not think they had much to fear from German competition; still it would be necessary to march with the times and abandon antiquated processes.

Mr. PHILIP HARTOG said they had heard a good deal of the ridicule cast by manufacturers on the system of teaching as carried out in university laboratories, but it seemed to him that it was not so much the fault of the system as the fact that manufacturers expected too much. They expected that a student should not only know, but that he should understand technical processes which could only be learnt in modern works. After an engineering student at Owens College had served three years as a student, he was supposed to have at least three years' training in a civil engineer's office before he was competent to fill any position requiring a knowledge of that profession; and it was the same with a chemical student, who, before he was called upon to take a responsible position, should be taught the technical part of his profession.

Dr. DREYFUS quite agreed with all that Dr. Hewitt had said with regard to students receiving a secondary education before passing into technical schools, and he thought one of the greatest defects in the present system of technical instruction was the inefficiency of the teaching staff which was principally owing to the small salaries offered.

Mr. J. H. REYNOLDS (director of the Manchester Technical School) said he endorsed all that had been said by Dr. Hewitt with regard to the defects of the present system of technical education. His experience proved to him that the system of education as carried out in elementary schools was such that the majority of pupils were quite unfit to receive instruction in any particular branch of technical knowledge; and moreover students seemed to expect to attain proficiency in the course of a short session or two, sufficient to earn money. So long as that spirit prevailed it was hopeless to expect anything like success in technical education. Dr. Hewitt had referred to the students in Switzerland who had served three years in the works, and who were the very ideal of what students should be, inasmuch as they had experienced the difficulties they had to contend against, and had voluntarily gone back to school to acquire the scientific knowledge they knew the school was capable of imparting to them. Until a system of secondary education was established in England which would reach every child in the kingdom, both rich and poor, the technical schools would be a failure. In Zurich the pupils passed from school to school and were afterwards drafted into industrial works. The Chairman had referred to the proposed Manchester municipal technical scheme, which could only be made successful by allowing properly trained students to enter, and by securing their attendance for a sufficiently long time to get thoroughly well grounded in laboratory work before passing into the dyeing department, where they could have an opportunity of seeing work carried on in a practical manner. If technical education in England was to be brought to a successful issue, we must be prepared to spend money lavishly as in Switzerland, and if the German Government could spend such large sums of money, why could not Manchester if it were necessary? He was afraid that manufacturers did not realise the importance of this, and it was only when trade was bad that any effort was made to alter this state of things. The only note of opposition he wished to raise against Dr. Hewitt's remarks was that to multiply technical schools, having regard to the lack of teaching power in the country, would only end in a considerable waste of money. They could only increase their number in proportion as well-organised secondary schools were established, and when they had achieved this he had sufficient faith in the intelligence of the people not to lag behind in the race of industry.

Dr. HEWITT was entirely at one with Mr. Reynolds as to the danger of increasing the number of technical schools. One of the practical difficulties was that every township wanted a fair proportion of the money set apart for technical education, and this might tend to multiply inefficient schools.

The CHAIRMAN, in reply, said the opinions expressed by Dr. Hewitt and Mr. Reynolds were quite in accord with his own. With regard to the pollution of rivers, he did not wish to set up any defence on behalf of chemical manufacturers, as they were bound to do all they possibly could to prevent the pollution of streams.

THE RECOVERY OF BY-PRODUCTS FROM COKE OVENS.

BY CHARLES DREYFUS, PH.D.

WITHIN the last twelve or eighteen months there has been a gradual fall in the prices of tar products, and specially of those used in the colour industry, such as benzenes and anthracene.

	Prices.			
	90s Benzene.	50s. Benzene.	Anthracene.	Sulphate.
1891.	s. d.	s. d.	s. d.	£ s. d.
January	4 8	3 6	1 4	10 10 0
December	3 0	2 0	1 2	10 5 0
1892.				
January	2 0	1 8	1 0	10 10 0
July	1 8	1 3½	0 9	10 0 0
September	1 7½	1 3½	0 9	10 0 0
November 1st	1 6½	1 3½	0 9	10 0 0

Most people in this country have been at a loss to account for this shrinkage in values, and various causes have been given as the reasons for it; our old friend, depression in trade, and bad trade in the foreign colour works have been trotted out by even responsible people; but the real reason of such depression—namely, a larger production—has been overlooked. It is to give the real reasons of this great shrinkage in values that I have prepared this paper, and in order that I may not be accused of over-stating the case, I will give you the sources from which my information is drawn: the principal sources of my information are the papers published by my friend Mr. Fritz W. Lürmann, engineer, of Osnabrück, in *Stahl und Eisen*, 4, 1892, and 18, 1892; also a pamphlet published by Mr. Ch. Demanet, C.E., manager of the Havré Colliery, near Mons, and which I owe to the kindness of Messrs. Semet-Solvay, and finally, private information obtained from friends in England and abroad, and which I have the right to use here to-night by permission of such friends.

The real reason of the depression in prices of benzene and anthracene is the large production of tar from the coke ovens abroad, the production of large quantities of benzene from such tar, and more especially from the gas of such coke ovens, and though England has been up to now the greatest producer and exporter of *Benzenes* and *Anthracene*, in the future I fear this will not be the case unless the English coke oven proprietors follow the example set to them by their colleagues abroad, and carbonise the whole or part of the "15,000,000 tons* of coal annually coked for the use of our ironworks" in ovens specially constructed for the recovery of the valuable by-products: tar, benzene, and ammonia.

HISTORICAL: PART.—I.

"More than one hundred years ago 'Stauf,' called the 'Kohlenphilosoph,' made a successful attempt to recover

the tar formed in the coking of coal." The ironmasters, engineers, and chemists all over the world have given much time and great attention to the question of coke-oven progress, with special regard to obtain by-products, and their experimental work in this direction extends back 35 years (this Journal, 1884, 601—606; also 1835, 451—452.) "Appolt, Semet, Coppée, and others have constructed ovens which have been for 30 years in very general use in Germany, Belgium, and France, whilst in Great Britain nothing seemed to shake the belief of iron-smelters in the infallibility of the bee-hive ovens. But even on the Continent it was thought that any attempt at condensing tar and ammonia must necessarily be fatal to the quality of the coke. Only quite recently has this belief been thoroughly shaken."

Thus, said Lunge, in his second edition of "Coal Tar and Ammonia," edition of 1887, and I can only add my testimony to his, that the coke produced in the ovens where by-products are recovered is now declared to be equal in quality to the coke from bee-hive ovens.

The French first, and the Germans afterwards, took up this question, and it has made slow but sure progress with them. The plant for the recovery of tar, benzenes, and sulphate of ammonia is not simple, and requires the greatest attention. The fear was entertained that by the introduction of these methods the coalowners would have to add chemical works to their mines; this plant increases considerably the primary cost of the coke ovens; then again, the coal-mine owners did not know what a ready market existed for the disposal of the by-products. The value of the recovery of the by-products has become clearer and clearer within the last 10 years, and the greatest praises are due to Mr. Hässener and Dr. Otto for their efforts in that direction. This latter gentleman has erected, for account of his own firm, as well as for others, a great number of Hoffmann-Otto ovens. These ovens are now at work over seven years, and the installation is so carefully planned that they give everywhere the greatest satisfaction.

II.—PROGRESS MADE IN THE DIRECTION OF SUCH OVENS.

The Hoffmann-Otto coke ovens exist now in the greatest number in Germany; they are the ovens worked in connection with Siemens regenerators. The following figures will show how this extension has taken place:—

	Ovens at Work.	Ovens in Construction.
1884	40	120
1885	210	140
1889	605	..
1892	1,205	..

Of these 1,205 ovens there are at work:—

	Ovens.
1. In the Ruhr district	470
2. In Upper Silesia	705
3. In the Saar district	30
	1,205

The firm of Dr. C. Otto and Co., of Dahlhausen, undertakes the construction of a group of 60 Hoffmann-Otto ovens with the necessary machinery and appliances for the recovery of the by-products (of which steam engines, gas exhausters, ventilators, and pumps are in duplicate) for the sum of 700,000 marks (about 36,000*l.*), of which about 15,000*l.* are for the ovens themselves, and 21,000*l.* for the condensation plant of by-products.

One Hoffmann-Otto oven can be charged with 6½ tons of coal, and requires 48 hours to work off; therefore in one

* See Lecture by Sir Lowthian Bell delivered at the Autumn meeting of the Iron and Steel Institute this year.

year the following amount of coal is coked, and by-products recovered :—

	One Hoffmann-Otto Oven.	A Group of 60 Ovens.
	Tons.	Tons.
1. In the Ruhr district	1,125	67,500
2. In Upper Silesia	1,170	70,200
3. In the Saar district	960	57,600

The yield from the dry coal is :—

	Coke.	Tar.	Sulphate of Ammonia.
	Per Cent.	Per Cent.	Per Cent.
1. In the Ruhr district	75-77	2.3-3	1.1-1.2
2. In Upper Silesia	65-70	4-4.5	1.0-1.15
3. In the Saar district	68-72	4-4.3	0.8-0.9

One ton of dry coal yields therefore an average of about $14\frac{1}{4}$ cwt. of coke, 10 gallons of tar, and 25 lb. of sulphate of ammonia.

One Otto oven produces, therefore, per annum an average of 820 tons of coke, 44 tons of tar, and $13\frac{1}{2}$ tons sulphate of ammonia.

The production, use, and surplus gas is per day and per oven :—

	Production.	Use.	Surplus.
	Cub. M.	Cub. M.	Cub. M.
1. In the Ruhr district	1,000	600	400
2. In Upper Silesia	1,150	650	500
3. In the Saar district	1,000	600	400

It is reckoned that every 100 cubic metres of this surplus gas replaces 87.5 kilos. (about $1\frac{3}{4}$ cwt.) of coal in the heating of boilers. The saving in coal by the surplus gas for a group of 60 Hoffmann-Otto ovens is :—

	Per Day.	Per Annum.
	Tons.	Tons.
1. In the Ruhr district	21	7,560
2. In Upper Silesia	26 $\frac{1}{2}$	9,458
3. In the Saar district	21	7,560

Of this surplus must be deducted one-third for use by the condensing plant.

II.—SEMET-SOLVAY COKE OVENS.

I come now to another system of coke ovens, which are in use in Belgium, in France, in Germany, and in one works only in England.

The first ovens of this system were built in 1882 by Mr. Semet, at the Bellevue Pit, No. 2, belonging to the Ouest Mons Colliery Co., with a small set of six ovens, which were worked on trial for about one year. Since then the experiments have been carried out by the Solvay Co., with a set of 25 ovens erected close to the Havré Colliery. Finally, the Bois du Lac Co. have taken up on their own account the working of this plant, which has now been greatly enlarged; the Semet-Solvay system has thus entered definitely into industrial practice. The following are the ovens at work of this system :—

100 ovens at Havré, near Mons.
26 " Seraing (Société John Cockerill).
25 " Ghlin (Société des Charbonnages du Nord du Flemin).
24 " Ruhrort (Société Phoenix).
39 " Northwich (Brunner, Mond, and Co.)
205 ovens.

There are in construction this year the following ovens of this system :—

50 ovens at Drocourt (at Henin Lietaud, France).
15 " Syracuse (Solvay Process Co.).
24 " Ruhrort (Société Phoenix).
26 " Seraing (Société John Cockerill).
25 " Jemeppe, near Liège (Charbonnages des Kussales).
140 ovens.

From the fact that the Phoenix Co. and the Société John Cockerill are erecting a second set of these ovens, I would conclude that the system gives full satisfaction. The construction of the Semet-Solvay ovens permits of a stronger formation of the covering masonry, a very high temperature can be attained, and good coke can be obtained from poor coal.

The cost of the oven itself, with fittings, steam ram, rails for the same, &c., can be estimated at 160*l.* per oven. This figure is not high, considering the large production of coke, which amounts to 100 tons per month per oven. To this estimate must be added the cost of the apparatus for the recovery of the by-products, which is about 100*l.* per oven. Each oven takes a charge of 4 tons of coal, and the coking is finished in 22 hours; the yield of coke is a maximum, and corresponds to the theoretical yield owing to the air tightness of the ovens.

At the Havré works, with coal containing 16 to 17 per cent. of volatile matter, the yield of coke averages 81 per cent.; in this figure are not included small coke and breeze. The coke is absolutely the same as that produced in ovens of the ordinary type; the by-products vary in quantity, according to the nature of the coal used. At Havré, where poor coal is used, the average yields are :—sulphate of ammonia, $13\frac{1}{2}$ lb. per ton of coal used, and 31 lb. of tar. Through the kindness of Mr. Mond, Mr. Gustav Jarmay, managing director of the Northwich works, has communicated to me the following figures of the average yield of by-products obtained in the Semet-Solvay ovens in use at Northwich :—"For the last half-year we have recovered ammonia equal to 12 kilos. (27 lb.) sulphate per ton of coal, and 40 kilos. (88 lb.) of tar per ton. Our ovens are the oldest type of Semet-Solvay, and at present are out of repair, as we intend to replace them by the new type of Semet-Solvay ovens, and we quite expect that the yield of ammonia and tar will be better after the alterations."

III.—EXTRACTION OF BENZENE FROM THE GAS OF COKE OVENS.

It is now about three years ago, that besides tar and ammonia, benzole was directly recovered from the gas of these ovens. The plant for this process has been devised by Mr. Frank Brunk, C.E., of Dortmund. The process is kept a secret, but my friend, Mr. George E. Davis, and others who have studied this question years ago, will know probably what that secret consists of. So much, however, is known that between 3 kilos. (7 lb.) and 7 kilos. (16 lb.) of 90 per cent. benzene are recovered from the gas of one ton of coal coked. The quantity varies, of course, according to the nature of the coal; these figures offer nothing abnormal when it is known that $12\frac{1}{2}$ kilos. (27 $\frac{1}{2}$ lb.) of 90s benzene can easily be obtained from the gas of one ton of good coal, distilled in an ordinary gasworks retort. (See Lunge, page 31.)

It is stated that the cost of erecting the benzene recovery plant is 250*l.* per oven (the Brunk system). Taking the present coke ovens as 1,205 (I have been informed there are now 1,350 Hoffmann-Otto ovens at work in Germany only, and that more are in course of construction). The quantity of coal these 1,205 ovens

can coke per annum is 1,382,400 tons: taking only the minimum yield of 3 kilos. of benzene per ton of coal, the yield in benzene, from the gas alone, would be 4,147,200 kilos., or over 1,000,000 gallons. I do not think there is quite as much as this quantity produced in Germany from coke ovens as yet; all the ovens not being arranged to recover the benzene from the gas, but I believe if we take Belgium and Germany together, there is not less than 1,000,000 gallons of benzene, and principally 90s quality, produced at present already from coke ovens alone; there is no doubt that this production of by-products is on the increase, because the Semet-Solvay system of ovens can be put down at a moderate figure, including the recovery of all by-products, tar, ammonia, and the extraction of the benzene from the gas. The cost of an oven, including all, would be about 260*l.*; the by-products, after deducting supplementary costs, yield 72*l.* per annum as net profit (this does not include the extra profit from the extraction of the benzene from the gas).

The recovery of by-products is not only of importance to the tar and colour industries, but it is of enormous value to agriculture. If we take into consideration the great profits realised in this industry (notwithstanding the lower prices now ruling), and which on tar and ammonia alone are over 40 per cent. on the cost of the plant, as we will show later on; if we add to this the profits on the benzene from the gas, we come to the conclusion that this recovery of by-products from coke ovens must go on increasingly. The demand for sulphate of ammonia and for tar is such that all the coke ovens in Germany, and even in England, if they were to recover their products, would find a ready sale for them. The actual daily consumption of pitch in Westphalia alone is 150 tons, which would take already the tar of 3,000 ovens.

Sulphate of ammonia is a valuable manure; in Germany the consumption of nitrogen containing manures has been as follows:—

	1887.	1888.	1889.	1890.
	Tons.	Tons.	Tons.	Tons.
Sulphate of ammonia ...	33,865	35,564	35,555	33,788
Nitrate of soda.....	194,619	259,482	320,820	330,366
Guano.....	71,880	58,261	54,062	46,444

If all the nitrogen in the above manures could be replaced by sulphate of ammonia it would mean that 285,000 tons of sulphate of ammonia would be required. The total quantity of sulphate of ammonia produced till now per annum from coke ovens is only 17,500 tons, and if all existing ovens in Germany were to recover by-products, the total annual production of sulphate of ammonia would only be 120,000 tons.

If we take the price of tar at 10*s.* per ton; of sulphate of ammonia at 10*s.* per cwt.; then the yearly income from a group of 60 Otto ovens would be:—

	For Tar.	For Sulphate.	Total.
	£	£	£
1. In the Ruhr district.	990	7,800	8,790
2. In Upper Silesia	1,500	8,000	9,500
3. In the Saar district .	1,200	4,920	6,120

This would give for one Otto oven a gross income of:—

	£
1. In the Ruhr district.....	115
2. In Upper Silesia.....	165
3. In the Saar district.....	102

From the above have to be deducted general expenses and sulphuric acid used for sulphate making, which are estimated at 50*l.* per oven, leaving therefore a net profit of over 100*l.* for by-products per oven, not including benzene.

There existed in 1892 in Germany, 16,947 coke ovens, of which 15,726 were at work; there are, therefore, at present barely 10 per cent. fitted up for the recovery of

by-products. It is estimated that the production of coke in Germany was, in 1891, 7,700,000 tons; if the whole of this coke had been produced in ovens fitted up for the recovery of by-products, Mr. Lürmann estimates the net profit from tar and ammonia alone (without taking into account either the benzene or the extra gas useful for other heating purposes) at 1,440,000*l.*

I would put the matter in a different way to prove how profitable this industry would be to this country. The best coke ovens without recovery of by-products give 60 tons of coke per month, according to information which I consider reliable. Suppose that the construction of such an oven costs 80*l.*; therefore the capital required for putting up ordinary ovens producing 100 tons of coke per month, would be, without recovery of by-products, 133*l.* 6*s.* 5*d.* for the Semet-Solvay oven, with recovery of by-products, the cost is 260*l.* for 100 tons coke produced per month, 126*l.* 13*s.* 7*d.* more capital is expended; these 100 tons of coke yield in by-products, after deducting supplementary cost, 6*l.* per month, or 72*l.* per annum, which is 57 per cent. of the additional capital spent for the same production. If to this we were to add the extra available gas of which one-half is sufficient for heating the ovens, and the benzene contained in the gas which can be extracted at very small cost, then these figures would come out still more favourably.

These figures apply to the poor coal used at Havré; in England, where better coal is available, better results are obtained, which can be tabulated as follows:—

	Sulphate of Ammonia.	Tar.
	Lb.	Lb.
Per ton of coal in England	27	88
" " Belgium	13½	31

The available gas in England would be larger also than in Belgium, our coal being so much richer in volatile matter.

Let us suppose that the 15,000,000 tons of coal which are coked per annum in England were treated in ovens of the Semet-Solvay type for recovery of by-products, we should obtain sulphate of ammonia, 180,000 tons, and in tar, 130,000,000 gallons; we should have surplus gas available, equivalent to one-fifth of the total coal consumed, and benzene from gas in such quantity that I fear to mention the figure.

The Board of Trade returns for 1890 (the last issued), give the quantity of coal used for gas making as 10,242,317 tons. This applies to authorised companies, but as there still are a large number of others, it is probable that the above total would reach 11,000,000 tons. If instead of the present system of working, gas were produced for sale by Semet-Solvay ovens, the coke could be used for metallurgical purposes, and the gas could be produced much cheaper than at present. If, finally, all the coal used in factories, works, and houses for heating purposes, and for the production of power, were coked, the gas and the coke produced would be available for heating and lighting purposes; we would do away with fogs and smoky towns, and the cost would be less than at present. I throw these suggestions out and they merit the consideration of all thinking men whether politicians, sanitarians, engineers, chemists, or manufacturers.

If we in England, using annually such an enormous amount of coal, were to recover the by-products, our profits would be great, our agriculture and industry would greatly benefit by the progress, and our towns would have a bright and clear atmosphere, where it would be a pleasure to live, and I hope the time will come when this progress which I foresee will be an accomplished fact.

SESSION 1892—93.

Notices of Papers and Communications for the Meetings to be sent to the Local Secretary.

Meeting held in the Durham College of Science,
Newcastle, on Thursday, November 10th, 1892.

MR. ALFRED ALLHUSEN IN THE CHAIR.

Professor BEDSON made an informal communication, giving an account of some work undertaken by Mr. W. McConnell and himself on the gases enclosed in coal and coal-dust. The coal broken up into small pieces, and enclosed in an exhausted vessel, was heated to 100° C. for over 100 hours, and gave off gases amounting to 10 or 11 times its volume (about 300 cubic feet per ton), of which about one-sixth was marsh-gas. After this treatment the coal, crushed to dust, was similarly heated for 26 hours, and gave off more gas (nearly 20 cubic feet per ton), of which 18 per cent. consisted of marsh-gas and its homologues; analysis showed that members of the series at least as high as propane, $C_3H_{8.0}$, were present. The experiments seem to show that the coal parts more easily with the lighter hydrocarbons than with the higher homologues.

ON THE PART PLAYED BY CALCIUM CHLORIDE IN THE WELDON PROCESS.

BY G. LUNGE.

THE late Walter Weldon knew very well that the presence of considerable quantities of calcium chloride is essential to the recovery of manganese peroxide by his celebrated process. No doubt a good many observations had been made on that point in various works with which he was in communication, and probably many others have been made since his time, but they seem to have remained buried in the works' note books, and never to have been utilised for deriving distinct quantitative rules therefrom. The only quantitative statement on the amount of calcium chloride required for the Weldon process which I know of is that which I have received from Mr. Schaffner, of Aussig, and which is found in my "Sulphuric Acid and Alkali," viz., that there ought to be from 2 to $2\frac{1}{2}$ molecules of calcium chloride present for each molecule of $MnCl_2$. I thought it therefore advisable to investigate this question as far as possible, and this I have done with the assistance of Mr. B. Zahorsky. I shall now give a short description of our results.

The most natural explanation of the auxiliary part of calcium chloride is this, that it serves as a solvent for the

lime, which is so essential for the Weldon process. It is well known that lime is more soluble in hot chloride of calcium solution than in water, undoubtedly owing to the formation of an oxychloride. Crystallised calcium oxychloride has the formula $3CaO, CaCl_2, 15H_2O$, recently confirmed by Mr. Zahorsky, who found that no other crystallised oxychloride can be obtained. Quantitative statements on the solubility of lime in $CaCl_2$ solution have only once been published (by Post, in "Berichte," 1879, 1541), but they are extremely fragmentary, since only four observations were made, and the concentration of the solution was merely established by the hydrometer. We therefore commenced by making more complete observations on the solubility of CaO in $CaCl_2$ solutions of various strengths and at different temperatures, of which the following is a synopsis:—

SOLUBILITY OF LIME in Solutions of Calcium Chloride (expressed in grammes of CaO per 100 cc. of $CaCl_2$ solution).

Liquid.	Temperature in Degrees C.				
	20°	40°	60°	80°	100°
Pure water,	0.1374	0.1162	0.1026	0.0845	0.0664
5 per cent. $CaCl_2$	0.1370	0.1160	0.1020	0.0936	0.0906
10 " "	0.1661	0.1419	0.1313	0.1328	0.1389
15 " "	0.1963	0.1781	0.1706	0.1736	0.1842
20 " "	0.1857*	0.2243	0.2204	0.2295	0.2325
25 " "	0.1661*	0.3020*	0.2989	0.3261	0.3714
30 " "	0.1630*	0.3681*	0.3664	0.4112	0.4922

In the cases marked with an asterisk a precipitate of calcium oxychloride was formed which removed some $CaCl_2$ from the solution.

We notice that the solubility of CaO in solutions containing up to 10 per cent. $CaCl_2$ at the ordinary or a slightly raised temperature does not differ very much from that in pure water, no doubt because no oxychloride is formed up to that point. At higher temperatures the presence of $CaCl_2$ increases the solubility of CaO , and this takes place proportionately with the quantity of $CaCl_2$, except where the phenomenon is complicated by a precipitation of solid oxychloride. Otherwise from 40° C. upwards the concentration of the solution has more effect than a rise of the temperature.

Apart from CaO , a solution of calcium chloride can also dissolve protoxide and peroxide of manganese, and we shall have to refer to this later on.

After this preliminary work it was our task to construct an apparatus in which the part played by calcium chloride in the Weldon process might be experimentally studied in the laboratory under conditions sufficiently resembling those of actual practice. That this is no easy task is best proved by the fact that Weldon himself did not succeed in getting any satisfactory results so long as he worked on a laboratory or even on a semi-grand scale; and it is also proved by the complete failure of Post to establish a process even remotely similar to that carried on on the large scale. The task was, however, successfully accomplished, as we shall see, by means of the resources of our technical laboratory, which has indeed been expressly constructed with a view to similar investigations.

We possess a blowing-engine driven by steam-power, with a network of pipes and taps for distributing the compressed air in the laboratory. With one of these taps I connected a circular iron vessel, from which three vertical glass tubes carried the air to the bottom of tall glass cylinders (40 cm. high) placed in a large common water-bath, heated to 55°—60° C. The ends of the glass tubes were provided with many small perforations in order to divide the stream of air into many bubbles, and at the same time to thoroughly stir the mass, just as in a Weldon oxidiser. As it was important

to ascertain that exactly the same quantity of air passed through each of the three pipes, several check experiments were made with exactly equal quantities of manganese liquor and lime, keeping all other conditions as similar as possible, and the product was tested for MnO_2 in the usual manner. The result of three such experiments, carried on at the same time by means of the three branch tubes, was as follows:—66.14, 65.90, 65.90 per cent. MnO_2 . This very slight difference, which is no greater than in the case of very good analyses, proved that my apparatus fulfilled its purpose in this respect, viz., that tests made with it at the same time are really comparable with one another.

The material employed for our experiments was ordinary "still liquor" obtained from a works where chlorine is made in the old style from native manganese ore and hydrochloric acid. This liquor was neutralised with an excess of chalk and filtered; it then contained MnCl_2 corresponding to 114.84 grms. per litre. For each test 800 cc. of this liquor was in the end diluted to 2,000 cc., so that it now contained manganese corresponding to 45.93 grms. MnO_2 per litre, which is very nearly the concentration usual on the large scale. The 800 cc. of liquor was mixed with the exactly necessary quantity of milk of lime for precipitating all the manganese as Mn(OH)_2 , and then tested for CaCl_2 , whereupon the liquor was made to contain a certain proportion of the latter by either taking away some of the clear solution or else adding solid CaCl_2 . Lastly, exactly 1 mol.

of CaO to 2 mols. of Mn(OH)_2 was added, and the mixture was made up to 2,000 cc. It stood at the same height in all three cylinders. During the experiments the water carried away as steam was replaced, and the same level of liquid always kept up. When the temperature of the bath had reached 55° or 60° C., the air-blast was started, and continued for 10 hours. This is certainly much longer than is ever done in practice, but it was necessary in consequence of the low depth of the magma as compared with a Weldon oxidiser, and the best proof that, in spite of this unavoidable difference, our conditions of working sufficiently resembled those of manufacturing practice, is given by the excellent results reported below.

I do not quote several experiments made with turbid liquors, which exhibit irregularities on the small scale similar to those experienced in large work. The others are summarised in the following tables, where I give the average results of two parallel experiments for each single case. In every case the same quantities of manganese (= 45.93 grms. per litre) and of free lime (= 14.78 grms. = $\frac{1}{2}$ mol.) CaO to 1 mol. Mn(OH)_2 and of water were used, but the quantity of CaCl_2 was varied from 1 to 6 mols. to 1 mol. Mn(OH)_2 , and tests were taken every hour. The table shows the percentage oxidation of MnO to MnO_2 , giving always the average of two experiments, which never differed more than is unavoidable both on the small and the large scale (at most 3 per cent. MnO_2).

Molecules.	Hours.										
	1.	2.	3.	4.	5.	6.	7.	8.	9.	10.	12.
1. $\text{Mn(OH)}_2, \frac{1}{2} \text{CaO}$:											
+ 1 CaCl_2	56.91	66.14	67.71	69.84	70.60	72.49	73.78	75.23	76.11	77.25	..
+ 1½ CaCl_2	54.95	60.68	65.82	69.22	71.41	73.81	75.00	77.20	78.30	79.24	..
+ 2 CaCl_2	50.56	58.23	64.31	69.93	73.89	76.59	78.52	79.60	80.21	80.97	..
+ 3 CaCl_2	42.23	53.13	61.78	70.06	76.17	79.05	80.45	81.62	82.53	83.92	..
+ 4 CaCl_2	38.53	48.70	57.86	68.35	76.02	79.68	80.94	81.75	83.27	84.75	..
+ 5 CaCl_2	29.43	37.50	44.37	49.77	52.32	65.36	75.14	81.08	84.11	85.20	87.79
+ 6 CaCl_2	19.74	26.47	41.37	51.18	65.71	73.14	79.77	82.36	83.75	85.51	89.13

It is evident that in the first stages of the process the oxidation of MnO and MnO_2 , or more correctly speaking the formation of calcium manganite, is the more retarded the more calcium chloride is present; with 1 mol. CaCl_2 it is nearly three times as quick as with 6 mols. But this proportion steadily changes with the duration of the blowing process; after six hours there is an equilibrium among all various proportions of CaCl_2 , and further on the degree of oxidation rises quite regularly in proportion to the quantity of CaCl_2 present. With 1 mol. CaCl_2 we find, after 10 hours' blowing, 77.25 per cent., with 3 mols. 83.3 per cent., with 6 mols. 85.5 per cent. Two experiments were continued for 12 hours in order to reach the maximum of oxidation, which was found = 89.13 per cent. with 6 mols. CaCl_2 .

In actual practice the oxidation at this stage (previous to the addition of the "final liquor" which we did not make, not to complicate the conditions) rarely exceeds 79 or 80 per cent. This is attained in very large oxidisers in two hours, in smaller ones in three hours, and in our small apparatus in six hours. It will be conceded that this is an exceedingly good result and entitles us to draw conclusions not merely for our small experiments but for actual practice. My conclusion is: that 3 mols. of calcium chloride to each mol. Mn is the most suitable proportion for the oxidising process. Below 3 mols. the process is essentially retarded, an addition of more than 3 mols. is more difficult to manage, and does not give a very large gain. Still there is no doubt that the operation ends all the more favourably, the more CaCl_2 is present.

The next question is, what is the cause of this favourable action of calcium chloride? The explanation which suggests itself from the first, and which was also given by Weldon himself, rests on the fact that CaO is more soluble in hot CaCl_2 liquor than in water, and that the oxidation must be all the more facilitated the more CaO there is in solution. If this is the only and all-sufficient explanation, then other similar solvents for CaO must act in a similar way. We cannot employ the best solvent for lime, viz., cane sugar, which, of course, entirely prevents the oxidation of MnO and MnO_2 ; the only substances which I found applicable here are the chlorides of sodium and potassium. Solutions of these, if not containing more than 5 or 10 per cent. KCl or NaCl , dissolve at 50° C. about 30 or 40 per cent. more lime than pure water, or almost exactly as much as a 10 per cent. solution of CaCl_2 , as proved by a number of special determinations which I leave out here. We now made three parallel tests, charging our three cylinders with the same quantities of manganese and lime as before, but adding to No. 1, 100 grms. CaCl_2 ; to No. 2, 100 grms. NaCl ; to No. 3, 100 grms. KCl per litre, which solutions would dissolve almost exactly equal quantities of lime. The three cylinders were heated in the same bath to 55° C.; air was blown through for eight hours, and the product analysed with the following results:—No. 1, 77.2 per cent.; No. 2, 69.41 per cent.; No. 3, 69.02 per cent. MnO_2 .

Although the same quantity of CaO was dissolved in all three cases, the advantage shown by the CaCl_2 in comparison with KCl and NaCl is much too large to be ascribable to an accident, looking at the absolute uniformity of all other

experimental conditions. This makes the assumption that the calcium chloride acts exclusively as a solvent for CaO very improbable; nor would this in any way explain the delay of the oxidation produced in the initial stage by an increased quantity of CaCl_2 .

We must therefore look for something else, and we naturally turn at once to the oxides of manganese themselves, whose solubility in CaCl_2 solutions was very early observed by Weldon (Chem. News, 20, 109). We have confirmed this; we have, moreover, found that the solubility of Mn(OH)_2 increases with the concentration of the CaCl_2 solution. The solution formed is colourless and turns brown on addition of chloride of lime. Weldon has noticed that any manganous salt, whether MnCl_2 or the solution of MnO in CaCl_2 solution, retards the oxidation of the Mn(OH)_2 suspended in the liquid, but that the simultaneous presence of lime quickens the oxidising process, by which a "port wine" coloured liquid is formed which Weldon took for a solution of calcium manganite in calcium oxychloride solution.

We have prepared that port-wine solution directly from the materials. In the case of a concentrated CaCl_2 solution it is amber-coloured, and there is no precipitate formed on boiling. Exposed to the daylight the clear liquid becomes gradually turbid and deposits a large quantity of MnO_2 (or calcium manganite). By the addition of water the colour is changed into dark brown, and it now yields a precipitate when heated. Hydrogen peroxide produces an evolution of gas and a vermilion-coloured precipitate. Ammonia gives no precipitate. Hydrochloric acid gives first a brown liquor, with evolution of chlorine, then the colour turns lighter, a green colour being temporarily formed. Sulphuric acid produces a precipitate of calcium sulphate, which also shows a transient green colour. Sodium sulphate produces a black precipitate.

Some of these reactions, especially the decomposition in daylight, seem to show that we have not to deal with a simple solution of manganese dioxide or calcium manganite in calcium chloride, but with a manganese dioxychloride, perhaps of the formula $\text{Cl-Mn-O}_2\text{-OCl}$.

The just-mentioned opposite behaviour of solutions of manganese, monoxide, and dioxide in calcium chloride during the oxidation of manganous oxide by oxygen seems to permit us to give the following explanation of the retarding action of an excess of calcium chloride in the commencement of the operation. Calcium chloride dissolves some Mn(OH)_2 , and this solution acts in a retarding way upon the oxidation of the suspended Mn(OH)_2 by atmospheric oxygen. The more CaCl_2 there is present the more Mn(OH)_2 is dissolved, and the more the retarding action of this solution is exercised. But as the oxidation is merely retarded, not stopped, gradually more and more MnO_2 (or rather CaMnO_3) is formed, which is also partly dissolved in the CaCl_2 solution, and yields the "port-wine solution" in which the oxidising action is accelerated. Thus, after a certain time, the retarding action of the MnO solution is compensated by the accelerating action of the MnO_2 solution, and later on the latter becomes prevalent. But at this point the circumstance comes into play that the quantity of MnO_2 entering into solution is also increased in proportion to the quantity of CaCl_2 present; therefore, in the latter stages the acceleration of the oxidation must increase with the quantity of CaCl_2 .

Several attempts were also made to clear up the nature of the "stiff batches" which used to occur frequently years ago, but are rare now, since it has been recognised that their formation can be prevented by keeping a proper quantity of calcium chloride in the mass, and by good blowing. The idea (suggested by Post) that thick batches were caused by the formation of solid oxychlorides is utterly untenable. Oxychloride does not separate out when calcium chloride is deficient, but only when it is present in excess, and even then only in far more concentrated solutions (as shown in the first of our tables) than ever occur in the Weldon process. Moreover, we found by filtering a "stiff batch," accidentally obtained, that the filtrate contained the full proportion of CaCl_2 , but a deficiency of CaO ; hence any separation of oxychloride was out of the question. We obtained even a stiff batch

by blowing air through a mixture of pure Mn(OH)_2 , free from calcium chloride, with a little more than its equivalent of Ca(OH)_2 . The analysis of a filtered sample showed 30.12 per cent. CaO , 11.11 Mn as MnO_2 , 41.32 total Mn, calculated as MnO_2 . There was thus more than 3 CaO present to 1 real MnO_2 . It seems that a combination of lime is formed with manganese protoxide, or else a very basic manganite, but we do not venture to pronounce a positive opinion on this question, which will probably be further investigated in the Zurich laboratory.

DISCUSSION.

Mr. STUART said that many years ago at Hebburn they made careful tests of batches worked on the manufacturing scale with varying amounts of calcium chloride, and had come to the conclusion that from 1.7 to 2 equivalents of calcium chloride to one of manganese chloride was the most suitable proportion. Thick batches arose when the proportion of calcium chloride was too small.

Mr. MARTEN pointed out that two equivalents of calcium chloride to one of manganese chloride was 3 of calcium chloride to 1 of manganese hydrate, as the decomposition of manganese chloride formed calcium chloride.

The CHAIRMAN said that excess of air appeared to act in the way of preventing thick batches, and thus counteracting the effect of a deficiency of calcium chloride.

Mr. RENNOLDSON thought the concentration of the solution would probably have some influence on the result.

Further discussion was adjourned until next meeting.

SESSION 1892-93.

Tuesday, Dec. 6th (Edinburgh):—Discussion on Mr. D. R. Stewart's paper, "The Flash-point and Heat of Burning of Mineral Oil."

Meeting held in the Societies' Rooms, 207, Bath Street, Glasgow, on Tuesday, November 1st, 1892.

MR. CHAS. A. FAWSITT IN THE CHAIR.

THE FLASH-POINT AND HEAT OF BURNING OF MINERAL OILS.

BY D. R. STEWART.

In examining a burning oil, the first thing to investigate is whether the oil is safe to handle and to burn in ordinary lamps, and after that, what light it gives, &c. The safety of an oil is determined by taking its flash-point as it is called. What the flash-point is meant to be is the lowest temperature at which an explosion of the vapours given off can take place when a light is applied to the mixture

of air and vapour. At this temperature there is a flash of flame going immediately out. A somewhat higher temperature is required to evolve vapour sufficiently fast to keep up a constant flame. The lowest temperature for this is sometimes called the firing-point. The old method of taking the flash-point, fixed by Act of Parliament, was by gradually heating the oil in an open cup, partly screened from draughts, and applying a light at intervals. During the experiment, the vapours first given off diffused away into the atmosphere, and a point far above the true flash-point was got, and this, of course, gave a false impression as to the safety of the oil. This method was not rejected on this account however, but because different experimenters could not or did not strike the same point. I do not know the origin of this test, but if it was not designedly invented to deceive the public and let dangerous low-flashing oil into the market, that at any rate was the result of its adoption. The present method fixed by Parliament is the close test of Sir Frederick Abel. In this case the cup is kept covered when being heated, and two little holes are opened for a moment when the light is applied; we get the true flash-point, the lowest temperature at which we may expect an explosion; and different experimenters get the same result.

To fix 100° F. as the minimum safety point for oil in our climate, was, I think, a very reasonable thing; but to change the safety point when the correct method of testing was adopted, was very absurd. 100° in the old test was about 73° in the new, according to certain experimenters, and the minimum for the new test was fixed at 73°; that is, the old test, giving an indication false by 20° or 30°, was used for fixing the new safety point as if it indicated the truth. What naturally fixes the safety point for any country is the highest ordinary temperature of the climate. An oil flashing at or under ordinary summer temperatures is dangerous to handle, let alone to burn. If temperature in houses is for months at 80°, 73° flash-point oil is as dangerous as naphtha. For safety in lamps we have to add the heat developed by burning, and besides that, add a little for safety to put the oils fairly out of the range of possible explosions. The common high temperatures of this country, 70° at least, plus the heat developed in the oil reservoir by ordinary lamps in ordinary dirty order (20° at least if of metal as recommended by Abel and Redwood) plus 10° to put the flash out of danger, gives 100° as the lowest temperature which can be allowed with any security for the flash-point, Abel test, for oils for ordinary household use. This takes it for granted that oils are safe in proportion to their flash-points, which is a matter we must afterward discuss.

The crude oils, whether shale or petroleum, from which our burning oils are manufactured, contain a considerable proportion of volatile oils, called spirit or naphtha, which vaporise or boil at comparatively low temperatures. These have to be separated in the refining of the oils, otherwise burning oils would flash or give off combustible vapours at ordinary temperatures. The separation of this volatile spirit is a simple matter, happening of its own accord in distillation; and in Scotland in the manufacture of paraffin oil from shale there is no temptation to let any pass into the burning oil, for this spirit or naphtha is always in demand, and often commands a better price than burning oil. As far as I know, however, Scotch manufacturers have kept the flash-point about 100° as a minimum, whether naphtha was cheap or dear. Scotch paraffin oil generally flashes between 100° and 125° F. In America and elsewhere matters are different. Foreign petroleum is produced in such quantities that the naphtha production is far beyond what is required. There is therefore a great temptation to put in as much naphtha among the burning oil as possible. A great bulk of American petroleum is sent into this country between 73° and 80° flash-point. The petroleum trade in America has been practically in the hands of one great organisation, which, of course, had no difficulty in believing that what suited it was good for the world. Manufacturers and merchants at home and abroad like to have freedom to sell a low-flash consignment of oil if by any chance it should be made, and the Government does not want to hamper the trade, or do anything that would increase the cost of light unless it sees undoubted danger. There is no great class

whose interest it is to see that the flash is kept high enough, and great and powerful interests are all ranged on the other side, so that the interest and safety of the people are neglected and the safety point fixed far too low.

The temperatures of 73° to 80° are common summer temperatures, and even common winter temperatures in rooms after the lamps are lighted and the doors shut, particularly in the upper strata of the rooms, the position in which lamps are often placed, on the mantelpiece of the poor or the brackets of the rich. At these temperatures there is an explosive mixture over the surface of ordinary petroleum, whether in ship tank, barrel, tin can, or lamp funnel.

For the poor, with the petroleum flashing at 75° or so, there is constantly lying in wait the possibility of an explosion. In hot summer weather it is always there, only waiting for the accidental touch of a light; and throughout the year, summer and winter, with every lamp using these low-flashing oils, as a general rule once every evening, as the oil warms with the burning, the explosive mixture exists for some little time, and often it will exist for hours. The danger is therefore not a rare one; it is a thing of every-day occurrence. So it is not at all surprising that explosions and fires in petroleum ships should not be rare; and that in London and other towns where cheap petroleum is much used, lamp explosions should not be infrequent. The question rather is, why are accidents not more frequent? and the answer, I fear, is that even the most ignorant people are more intelligent than the Government, and have been taught by dire experience to treat ordinary petroleum as a dangerous liquid. The lowest flashing petroleum is in some respects more dangerous than gunpowder, for the powder only ignites on applying a light directly to it, while the petroleum insidiously exhales its vapour all round where no danger could be anticipated. But surely it is something approaching a national crime to put into the hands of the poor, the least intelligent of the people, a liquid which gives off an explosive vapour at ordinary temperatures, and to give it practically a Government certificate of safety. Yet that is exactly what is done. There are many deaths every year from ordinary petroleum, none of which would have happened if the safety flash-point had been left at 100°. Now, who is responsible for these easily preventable deaths, as well as all the destruction of property? You and I, gentlemen, if we don't speak out.

The better brands of petroleum used by the rich, to be got for a trifle more per gallon, are homogeneous in their nature, and their flash-points range from 100° to 125° F. or so. With them, under ordinary circumstances, the explosive mixture is never lying in wait, and there is no danger with them whatever if treated in anything approaching a reasonable manner. Under such circumstances our hope would naturally be in the Government, but unfortunately it is there that the great impediment lies.

From Eyre and Spottiswoode can be got for three halfpence a Report by Abel and Redwood on lamp accidents. How lamps may be modified to prevent accidents is the subject, but they fully discuss the influence of the oil.

They give details of 28 accidents, with flash-point of oil as far as can be ascertained. They found only one high-flashing oil 110°, and the accident was a case of over-setting. The highest flash-point got besides this was 88°. There were 23 cases of lamp explosion all of which, as far as could be ascertained, were from low-flashing oils. So their own table proves that 73 and even 88° are far too low for safety, and that over 100° is safe; yet they do not point this out but talk as if the reverse were proved.

They fail to point out the danger in the ordinary every-day handling of low-flash oils and talk as if the only risk were explosion in the lamps.

They argue that 73°, or a lower point, is safer than anything higher (page 5) and that this safest oil is at its greatest safety when heated far above its flash-point, so that the air is all expelled by the evolved vapours (pages 5 and 9). Now any person of common sense can see that this for common lamps and every-day use is very absurd. I quote their words, "If the flashing-point of the oil used be below the minimum (73° Abel test) fixed by law, and even if it be

about that point or a little above it, vapour will be given off comparatively freely, but the mixture of petroleum vapour and air formed in the upper part of the reservoir of the lamp will probably be feebly explosive in consequence of the presence of an excess of vapour. On the other hand, if the flashing-point of the oil be comparatively high the vapour will be less readily or copiously produced, and the mixture of vapour and air may be more violently explosive, because the proportion of the former to the latter is likely to be lower, and nearer that demanded for the production of a powerfully-explosive mixture." That is, they are of opinion that the lower the flash the safer the oil. If there was anything in the argument, 73° should be fixed as *maximum* and not *minimum*. Their highest flash was only 88°, and consequently the greater violence of their highest flashing oil over their lowest was a matter of no moment, as even 88° is dangerously low; but they make the statement as if it were of great importance, and put it so generally as to give the impression that the higher the flash the greater the danger. Common sense would advise a flash-point high enough to be out of the region of danger altogether. They do the very reverse. They go on to say, "Experiments have demonstrated that the burning of an oil of comparatively high flashing-point is more likely to cause heating of the lamp than the use of an oil of comparatively low flashing-point, in consequence of the higher temperature developed by the former, and of the greater difficulty with which some oils of that description are conveyed to the flame by the wick. It therefore follows that safety in the use of mineral oil lamps is not to be secured simply by the employment of oils of comparatively high flashing-points (or low volatility), and that the use of such oils may even in certain cases give rise to dangers, which are small, if not entirely absent, with oils of comparatively low flashing-point."

I am quite sure that this is a mistake they have made, and that as a general rule the very reverse is the truth. They fail to state the rule it seems to me, and give a rare exception as if it were the rule. Mr. Fox, present chemist to the Petroleum Association, and others, have made experiments proving them to be wrong. In all my experience I never found any corroboration of their statement. I give experiments in the Tables, proving that the law of the matter is that the lower the flash the more danger there is of a high temperature being developed.

In summing up the results of their investigations, Abel and Redwood say, "In one case the oil flashed at 73°, in one at 74°, in one at 77°, in one at 78°, in two at 79°, in one at 82°, in one at 83°, in one at 84°, in one at 86°, in one at 88°, and in one at 110°. Therefore in one half of the cases in which it was possible to determine the flashing-point of the oil, it was about 10° and upwards above the legal standard. In some of these instances the explosion was apparently of a more than ordinarily violent character."

Further on, in advocating metal reservoirs, they say, "Moreover, the heating of the oil does not necessarily increase the probability of the formation of an explosive mixture; on the contrary, any increased volatilisation resulting therefrom would have the effect of increased expulsion of air from the reservoir, so that the vaporous contents would be rendered inflammable instead of explosive. A lamp intended to be used with ordinary petroleum oil, and having an unprotected burner, is in the safest condition when the proportion of vapour to air is considerably in excess of that required to produce an explosion."

They say *safest*, when the oil according to their showing is heated far above its flash-point! But they are wrong in indicating that vapours would under ordinary circumstances be evolved in sufficient quantity to expel the air to such an extent as to prevent explosion. A certain temperature merely demands a certain definite pressure of oil-vapour, and when this is got evolution stops. Even with naphtha, a half-filled oil-can or lamp would not cease to be explosive, unless by the outward application of heat for the purpose. They themselves pointed out that many accidents were from oversetting, or from reservoir breaking. In the case of their so-called safest condition, if such accidents happened, there would be a sudden evolution of vapour all round, an explosion would certainly take place and vigorous combus-

tion ensue. Moreover before this safest condition could be reached by the heating of the lamp, in every case the state of greatest danger must be passed through. In a lamp full of oil the danger of an explosion might not be very great, yet still not insignificant; but when a half-filled lamp is lighted, as is habitually done by many people, the danger remains a long time, probably for hours, and the explosion, if it took place, might be the sharpest possible, whether with 73 flashing oil or 88. This is not a matter in which it is necessary for experts to instruct us.

Now, if a lamp of high-flashing oil were overturned, the lamp would likely go out, or, if the wick continued to burn, it would burn quietly on the pool of oil for some time without inflaming, it would not cause alarm, and would be easily extinguished. That is, unless the oil were highly heated by the lamp, as it was in Lord Romilly's case. His death was caused by a metal lamp without any non-conductor between burner and fount, and evidently intended to heat the oil to make it burn better, which it on that account certainly does. The table was overturned with lamp and papers on it, and the burner was so insecurely fixed that it fell out, allowing the oil to flow over the papers. In Scotland here I have heard of many cases of paraffin lamps oversetting, but I never heard of an explosion or fire resulting.

No doubt oil of 73° flash can be burned in proper lamps with perfect safety, just as naphtha can, but no manipulation of lamps would ever make naphtha or 73° flash petroleum safe for ordinary handling. We need never even talk of such a thing until the working man is able and willing to give a guinea for his lamp instead of a shilling as at present.

Mr. Redwood lately said:—"He had the honour of being associated with Sir Frederick Abel in some of his experimental work, and well remembered his expressing in his report a very distinct opinion that there was no grounds for considering that the minimum legal flash-point was not calculated to afford adequate protection to the public." (*Jour. Soc. Arts*, xl., 217.) I, unfortunately, could not get any such report from Eyre and Spottiswoode, or I would quote from the report itself.

Some time since I wrote to Mr. Gladstone on the subject, and the other day I got an answer from the Home Secretary "That he was advised that there are not sufficient grounds either of safety or convenience for an alteration of the existing flashing-point for mineral oils."

The oil required by the War Office has to be 105° flash-point as a minimum; lighthouse oil, 145°. Now, why does the Government supply its servants with such dangerously high-flashing oil if, according to the teaching of Abel and Redwood, 73°, or something lower, is safer? If our intelligent Government servants are not sufficiently protected unless they have a flash of 105°, how are the ignorant poor sufficiently protected by a flash of 73°? There seems to be something very far wrong somewhere.

Mr. Redwood's remarks to the Society of Arts are well worth reading. He appears to think the experiments made by the million every night are in favour of low-flashing oils, yet, judging from his own report, accidents are practically all from low-flashing oils.

Abel and Redwood are of opinion that metal lamps are best. The problem they set themselves seemingly was—how can ordinary dangerous petroleum be burned safely in lamps? Quite an impossibility. They suggest metal reservoirs strong enough to stand an explosion, and have low-flashing oil, well warmed by the lamp, to drive out the air with oil vapours, as before mentioned. Metal reservoirs are objectionable. You cannot see to fill the lamp without overflowing it. The smear itself is dangerous with low-flashing oils, particularly when it warms. It also causes the oil to syphon out by surface attraction, which it does with more speed than one would believe. Also, if the reservoir is a little too full, warning rapidly as it does in metal, the oil expands and must get out somewhere to produce a blaze, either through some chink of reservoir, or up the burner-tube to cause an alarming flare of light in the chimney that cannot be controlled or extinguished by screwing down the lamp. My opinion is we ought to have high-flashing oil, and we should have a glass reservoir with a non-conductor between it and the burner. Even although

the lamp were smashed, with the oil 20° under the flash-point, as it would naturally be in such a case, the danger of fire would be very small. But the glass reservoir might be protected by metal. Their proposal to protect the filling hole and burner-tube with wire gauze is very good, but it would be difficult to enforce it universally, or prevent it being torn out of cheap lamps. Then with a wick too small, as often happens in places far from the market, or with duplex lamp and one burner left without wick, as is sometimes designedly done, the train is laid for an explosion. The oil must be safe as well as the lamp.

The experiments I give were carried out to see the effect of flash-point on the heat developed in burning, and to get at that with certainty, I tried to make out the effect of other qualities, such as heavy oil being present, chemicals left in the oil, &c. When I commenced my experiments first I wished to investigate the matter very thoroughly, but was prevented. However, I tried a few experiments to satisfy myself, and these are what I have to give.

My aim was to have all the results exactly comparable. I used the same lamp with glass reservoir throughout. The table I give of the oils of different Scotch companies may possibly be an exception as they were tested previously; the lamp even in these cases was the same one, or one exactly similar. I took a new piece of wick for each experiment, clean and dry, and always of the same quality, and in the cases of first division of Table I. and first division of Table II., even from the same coil. Changing the wick each time was the only way to get comparable results, as I could not continue the same oil for a length of time; but by this way we do not get the full difference of good and bad oil, for some bad oils are cumulative in their bad results, as the impurities accumulate in the wick.

I wished to get the highest temperature possible for each oil, so as to get the differences accentuated. I soldered, therefore, a little tube to the metal outside the chimney, at the same level as the burner, put mercury in it, and a thermometer bulb in the mercury. If I took only the temperature of the oil in the reservoir I thought the error of experiment would be great from the effect of difference in draughts on a windy day and a quiet one, &c.

In doing first division of Table I. I did not take temperature of oil left in lamp at all, as I knew it was never high enough to be near the flashing-point of the oil; but having taken this in the case of petroleum, I supplemented these afterwards with the temperature results given in the second division of Table I.

The lamp with glass reservoir is a Young's duplex; and the metal lamp is a duplex exactly similar, I believe, to the one which caused Lord Romilly's death. After adjusting the flame of the lamp at first to its full height we did not touch it afterwards in case one experiment would get more care than another. The experiments and calculations given were made by my assistant, Mr. John Woodrow.

When a lamp burns badly it generally develops more heat than usual, the light is red instead of white, and the combustion is imperfect, producing a bad smell. This may arise from a bad lamp, the air supplied not being sufficient or not properly reverberated on the flame, or from the chimney being too short or so badly shaped as to give a back current inside the widened part; or it may arise from the lamp being dirty and air-holes partly filled; or from the wick being bad, damp, or dirty; or from the oil being polluted with a trace of vegetable or animal oil in the dishes used for measuring or filling; or from the oil itself being bad from refining chemicals being retained or heavy oil being present.

In the tables, I give the lamps burned with the air-holes free and also with the air-holes partly filled with candle-wick, so as to imitate the effect of a lamp in bad order. The result was often to decrease the light and always to increase the heat.

I give also the specific gravity of the oil, and the flash-point. The flash-point does not always rise in proportion to the specific gravity, comparing paraffin oils by themselves, or petroleum by themselves; for an oil of 800 sp. gr. say, may be either a comparatively homogeneous oil of that gravity, or it may be a mixture of lighter and heavier oils, with 800 as the average. The structure of the oils tested

is given in the columns for fractionation. My rule for fractionating is to make cuts with intervals of 25° or 50° C., but working with Fahrenheit thermometers my assistants erred from this a little, for which I am sorry; but all are done comparatively with each other. It is much better to fractionate in this way than to cut into equal measures, say 10 per cent. fractions, as one sees at a glance the structure of the oil. The effect of oil being not homogeneous in structure is shown in (7) where light special oil 782 is mixed with heavy marine sperm 830. The light was pretty well kept up, but the heat developed was much greater than with either oil separate. If the wick had been of poor quality the result would have been far more striking. A closely-woven wick fractionates the oil to some extent, and the residue in the wick and lamp tends to get heavier; so that an oil containing heavy oil with such a wick burns very badly after an hour or two, while a homogeneous oil burns well throughout. With a very good loose wick, the heavy oil rises pretty well, and the burning of badly-fractionated oil approximates to the well-fractionated. A well-fractionated oil is nearly independent of wick, one with heavy residue does not burn well unless the wick is very good. The burning oils (8—13) of first division of Table I. are all of similar quality, with fractionation similar to the two given.

In testing an oil in the laboratory all that boils over above 300° C. (572° F.) is looked on as hurtful to the burning in ordinary lamps. Ordinary paraffin oil has sp. gr. 808 to 815, but special lamps can burn oil of 830 or 840 quite well, and the flash of these is 220° or 230° F. They contain a considerable residue boiling over 572° (See (3).)

The expression "treated" and "untreated" which I have used refer to whether or not the oils were treated with acid and soda after the last distillation. Burning oils are greatly influenced by a finishing treatment. It gives them a pale colour and improves the smell. The oil settles quite clear, but retains sulpho-compounds of soda, and these have to be washed out as thoroughly as possible. Whether thoroughly washed or not the burning of the oil is always somewhat harmed by the treatment, and if much soda-compound is left in the oil, the oil is much the worse. The sulpho-compound decomposes in the burner, giving free sulphuric acid, which chars the wick, sometimes for an inch down the burner-tube. The wick at the top becomes quite acid to litmus. But sometimes the wicks are acid of themselves to begin, and acidity in the burner is not always from the oil. As a rough and rapid test for the amount of this decomposable sulpho-compound, I heat the oil rapidly to 330° , cool rapidly, and titrate the acidity. With care in doing the experiments all alike, the results are comparable. If left in the heat any time, the acid is given off as SO_2 , and disappears. I take 2,000 fl. gr. of oil and wash it afterwards with 200 fl. gr. of water. I titrate the water with centinormal soda, using methyl-orange as indicator, and the figures I give are the number of fl. gr. used. Experiment No. 11 was made for the purpose of testing the effect of much chemical retained. It was settled clear without further washing. The average C.P. is reduced from 19.6 to 14.6 .

Carefully fractionated homogeneous oils are low or high in flash in proportion to specific gravity and boiling point. To get at the influence of flash-point free from any confusing element I tried paraffin oil of similar quality, but varying in specific gravity, flash, and boiling point, and therefore exactly comparable. Nos. 1, 2, and 3 of Table I., first division, have flashes respectively 100° , 155° , and 230° . Burned with free burner the temperature was practically the same in all, being at burner 102° , 103° , and 104° respectively, giving the higher flash with the higher temperature. Even this little difference, I concluded, was from error of experiment, as I always got higher temperature with the lower flash afterwards, as in Tables below. One degree at the burner would only be a very small fraction of a degree when conducted to the oil, and diffused over it. When I tried similar oils with the air-holes partly filled, as lamps generally are, I was much astonished to find the lowest flashing oil give by far the highest temperatures.

The experiments being carried on at intervals as we happened to have time, the circumstances as to the weather, &c., varied, and the results vary a little one with another. I tried my very best to invent means of getting a high

temperature with high-flashing oils, as Abel and Redwood got for one experiment at any rate, but I failed. I wrote to Sir Frederick Abel, giving my experience, and asking him to give me a hint as to how I could repeat his experiments; but he answered that "he was altogether precluded at the present time to give any attention to the subject," and that he had forwarded my letter to Mr. Redwood. Mr. Redwood did not write in answer to my question, and I did not trouble him with another letter.

I thought if the oil were supplied freely to a lamp burning well, that the higher temperature should be got from the higher specific gravity and flashing-point, so I burned comparable oils with oil supplied at constant level, $2\frac{1}{2}$ in. below burner against 5 in., which is common enough in lamps, and I got the old result, highest temperature from lowest flash.

I tried American and Russian oils with the results shown on Table II. I tried the crucial experiment given in the last division of the Table. I distilled a sample of petroleum all over, and added naphtha from one half to the other half with the naphtha, and thus got comparable oils, such as I had of the Scotch, differing only in flash, we may say, with the result again of getting highest temperature with lowest flash-point.

I tried many experiments which I have not recorded, as each would have had to have been detailed separately; but all accorded with the results given.

My experiments leave no doubt on my own mind that Abel and Redwood's observations of a higher temperature from higher flashing oil was a mistake, and that the oils they compared had not been comparable. However high a temperature their high-flashing oil gave, I have no doubt a really comparable oil of low flash would have given a still higher temperature in similar circumstances. To render an oil flashing at 100° as dangerous as an oil flashing at 73° , it would have to produce a temperature in the oil vessel of 27° higher.

I have no doubt if all our oils, home and foreign, were made with high flash-point, it would render them safer in every respect. I have little doubt that to make all oils safe in this way would be a blessing to manufacturers, as well as to sellers and consumers. A demand for naphtha for enriching gas, or some other purpose, would soon be created; and, with ensured safety in use, the consumption of paraffin oil and petroleum would, I have no doubt, increase enormously. We will soon have factories driven by oil engines, working at the top of Highland mountains, and other out-of-the-way places, where coal as fuel is impossible. To give petroleum a chance of taking its natural place in the world, freedom from explosive vapour ought to be ensured, and I hope the manufacturers will soon see that this is to their own advantage.

I think myself it is an immoral thing for either individual or company to make or sell oil that gives off explosive vapours at ordinary temperature of house or lamps without labelling it as dangerous. If it were not for that report of Abel and Redwood, I would think that no sane man could look on 73° flashing oil as anything else but extremely dangerous.

It is a fact, of course, that high-flashing oils, which naturally burn cooler than low-flashing ones, can be contaminated (see 13 of Table I.) or burned in dirty lamps, so as to produce a dangerously high temperature; but with ordinary care of oil and lamps, I look on the 105° flashing oil of the War Office practically as safe as colza, or any other combustible oil.

More than a year since I tried to get samples of as many Scotch oils as I could. I give the results of my tests, showing all were of safe flash-point. Some, however, retained too much chemical, and would tend to char the wick and heat the lamp, but the experiments were carried out before the question of temperature was suggested to me. They should have the oils better refined before giving the final treatment, and be able to finish with less sulphuric acid.

I have not been able to carry out the series of experiments I originally planned, but I will continue to experiment as I have opportunity. But others should experiment also, and publish their results. It is a matter of too much importance to leave to the proclivities of a few individuals. Many

thoughts are suggested by my little array of experiments. These or a better planned series should be carried out by every oil chemist, so that the laws of the matter might be made quite definite and beyond dispute, and out of the region of mere opinion. Even educated persons have great diffidence in forming an opinion where scientific questions are involved, for although they are as capable of judging as experts, they do not know it, and this is a question on which they have been confused and misled. I have been greatly oppressed by my own responsibility in the matter—a responsibility brought painfully home to me by every death from lamp accident—and I had resolved to speak out my mind whether

I was opposed or supported by the Scotch oil trade. I think this Society should appoint a committee to draw up a series of experiments to be carried out by each member of the committee independently.

We should get from Parliament reliable and full returns as to deaths and fires from mineral oil, with origin of oil and flash-point as far as possible. I have no doubt whatever that all facts and experiments when collected and interpreted aright will further prove what I hold is proved already, that other things being equal, the higher the flash-point the safer the oil, and that 100° F. is the lowest flash-point that could with any confidence be adopted.

TABLE I,
SCOTCH PARAFFIN OILS.

	Oil Tested.	Air-Holes of Lamp.	Specific Gravity.	Flash-Point.	Candle Power.			Temperature of Burner.				
					After Burning.		Mean.

Obituary.

CHARLES THOMPSON, F.I.C., F.C.S.

A MEMBER OF THE SOCIETY OF CHEMICAL INDUSTRY.

THE subject of this brief memoir received his chemical education in the first instance in the laboratories of the Pharmaceutical Society in Bloomsbury Square, and subsequently, in 1881, became associated with Dr. C. R. Alder Wright, F.R.S., at St. Mary's Hospital, Paddington, firstly as articled pupil, and then as assistant. In 1885 he was appointed Demonstrator of Chemistry in St. Mary's Hospital Medical School, which post he held for nearly five years. During this period of about nine years in all he collaborated extensively with Dr. Alder Wright in several branches of scientific research, as well as various technical inquiries, as the result of which labours 18 memoirs and other papers were communicated by the two authors conjointly to the Royal, Chemical, and Physical Societies, the Societies of Chemical Industry and of Public Analysts, and the British Association, embodying the results of researches in various branches of work, more especially in electro-chemistry, metallurgy (alloys), and the chemistry of the soap manufacture.

These latter researches led in the spring of 1890 to his being offered the general management and scientific supervision of Messrs. Blondeau and Cie.'s factories for the manufacture of "Vinolia" products, a post the somewhat onerous responsibilities of which he ably discharged until shortly before his death, when the state of his health prevented his attending actively to work.

Charles Thompson died on Saturday, October 8th, unmarried, at the early age of thirty-one years, after a somewhat brief but painful illness. He was very successful as a teacher, his genial temperament and patience causing him to be highly esteemed and greatly liked by the students under his care. His energy and capacity for work were remarkable, whilst in private life his pleasing manners and social attainments greatly endeared him to all his friends. The writer especially looks back in memory to the nine years spent in almost daily companionship with him with feelings of pleasure mingled with regret that the career of one so amiable should be thus early and painfully cut short.

—C. R. A. W.

Proc. Inst. Civ. Eng. 110 (iv.) 21.

See under XIII., page 929.

PATENTS.

Improvements in Filters. B. M. Santurio, Buenos Ayres.
Eng. Pat. 10,314, June 17, 1891.

This invention relates to what are known as "earthenware" filters, the improvements referring principally to the construction of the permeable cylinder or vessel, which is here surrounded with permeable hollow screw threads leading from one end of the cylinder to the other. The liquid passes through the hollow screw in one direction, and returns by the inner cylinder in the other. There are arrangements for cleaning the filtering surfaces by flushing.—B.

Improvements in Filters. R. C. Sayer, Bristol. Eng. Pat. 14,609, August 29, 1891.

In the improved filter the porous material is placed in an inverted siphon, which may be attached to the bottom of the water reservoir by bolts, so as to be suspended in the filtered water reservoir, or, in large filters, where the weight of the unfiltered water reservoir is considerable, may be bolted to the sides of the reservoirs. By this means it is claimed that the cleansing of the porous materials is facilitated. When upward filtration is not desired, a straight tube is substituted for the siphon. Thus the siphon, or straight chamber, and retaining chamber will be outside both reservoirs, and either may be removed without disturbing the other, or either reservoir.—O. H.

Improvements in Water-Filtering Apparatus. W. C. Henderson, London. Eng. Pat. 14,843, September 2, 1891.

THE inventor claims "the combination, or arrangement and use, of a water-filtering apparatus, comprising means of supply of water, as from the stack pipe from a house roof, a chamber for sediment, divided from the filtered water chamber by sponges, sand, or other suitable filtering material, and reticulate screens through which the water filters by ascension, and means to draw off, overflow, and access for cleansing."—O. H.

Improvements in and in the Construction of Wood Trays for Filter Presses. J. Teggin, Longton, Staff. Eng. Pat. 15,747, September 17, 1891.

THIS invention relates to certain improvements in the details of the construction of wooden trays and grates used with filtering presses, the object being to construct such trays of less bulk and weight than hitherto.—B.

A New or Improved Filter. F. D. Tippetts, Birmingham.
Eng. Pat. 16,234, September 24, 1891.

THE body of the filter consists of two "nearly similar semi-ellipsoidal halves connected together by screwing." The body or case is open at both ends, one end having a funnel-shaped mouthpiece lined with india-rubber so that it can be attached to the nozzle of an ordinary tap; the other end has a short delivery pipe. Each half is charged with animal charcoal supported by layers of felt. For purposes of cleansing the body may be unscrewed and the charcoal replaced, or the rubber mouthpiece and delivery pipe may be reversed and the impurities washed out by a stream of water.—O. H.

Improvements in the Method of and Apparatus for Treating or Drying Artificial Manure, also applicable for Drying Grain, Minerals, and other Substances or Materials. B. L. Fletcher and J. Hoyle, Halifax.
Eng. Pat. 16,281, September 25, 1891.

THE apparatus consists of a vertical cylindrical vessel, containing a series of horizontal hollow plates of different diameters, one set of plates having central openings through which the material drops, whilst the other set of plates permit the material to fall over the outer edges. A central shaft carries scrapers or distributors of bristles, wire, &c. arranged at such angles that on one set of plates the material is worked towards the centre and on the other to the circumference. The plates are heated by steam or other suitable heating medium, and the material is dried during its descent through the apparatus.—O. H.

Improvements in the Construction of Vertical Stills for the Distillation of Ammoniacal and other Liquors or Liquids. J. Wright, Stockton-on-Tees. Eng. Pat. 18,533, October 28, 1891.

THIS invention relates to columnar or vertical stills, in which there are superimposed trays or platens with caps, over the edges of which the liquid flows downward, whilst the heated gases or steam rise upward through central openings. The improvement consists principally in making the caps of annular form, either circular or of any other shape, in order to enable the steam to rise on the inner as well as the outer edges of the caps, after forcing its way through the liquid on the trays, thereby considerably increasing the effective working surfaces within the casing.—B.

* Any of these specifications may be obtained by post by remitting sd.—the price now fixed for all specifications, postage included—to Sir Henry Reader Luck, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C.

Improvements in Apparatus for Separating from Liquors the Scum or Matter which rises to the Surface during Boiling or Heating. A. Chapman, Liverpool. Eng. Pat. 19,364, November 9, 1891.

THE object of this invention is to secure the skimming without loss of boiling liquids, more particularly of saccharine solutions, by means of the interposition of a strainer and a body of quiescent liquid between the scum and the boiling liquid. The inventor endeavours to utilise the fact that when liquids are boiled the scum or "feculencies" retreat from the hotter to the colder parts of the vessel, one of the arrangements being shown in the accompanying illustration.

APPARATUS FOR SEPARATING THE SCUM FROM LIQUIDS DURING BOILING.

A is the boiling vessel, W the heating steam coil, B a partition reaching down within a short distance of the bottom of the vessel, and some distance above the liquid when not boiling. From the top edge a cover plate C extends to another partition D in the skimming pan, reaching down to near the bottom of that pan. The strainer F lies across the pan near the upper part of the partition, and the side G of the pan near the boiling vessel forms a ledge very little higher than the level of the strainer F.

As the liquor in A boils, the froth and scum overflow the partition B on to the strainer F, where the scum is retained, and the purified liquor, becoming nearly quiescent, at E, returns over the ledge G for further boiling.—B.

Improvements in Thermostats or Instruments for Regulating Temperatures. A. Shiels, Glasgow. Eng. Pat. 20,368, November 24, 1891.

THESE improvements relate to the regulation of the steam valves of the refrigerating engines by a thermostat, the upward movement of the piston of the latter opening the steam valve of the engine by means of a slotted and balanced lever, while a spring brings down the piston when contraction takes place in the fluid in the thermostat tubes.

"In cases where the temperature in the refrigerating chamber, through an accident, rises far above the normal, the piston-rod of the thermostat, or a projection on it, may be made to strike a lever and open a valve leading to the sensitive fluid tank, so that the excess of fluid in the pipes may pass into the tank and thus prevent breaking or bursting of the apparatus."—O. H.

An Inexplosible Can for Inflammable Liquids. T. R. Shillito, London. Eng. Pat. 21,086, December 3, 1891.

THE can is so constructed that the neck is sealed by the liquid in use. Within the neck a tube extends downwards, terminating near the bottom of the can in a large mouth. From within the neck also, but lower down than the top of the first tube, a second tube extends obliquely upwards, terminating in a spout. Owing to the relative

position of these, the liquid, when poured from the can, must pass through both tubes, so that when the can is restored to the vertical position, there will always be liquid in the neck. The inventor claims that, in the event of the overflowing liquid taking fire the flame will not be communicated to the interior of the can.—D. A. S.

Improvements in or connected with Furnaces. T. W. Williams, Swansea. Eng. Pat. 2567, February 10, 1892.

THIS invention relates to certain improvements in the furnace described in a former patent (No. 539 of 1878), and its object is to obtain a more perfect combustion of the fuel. This is effected by making an opening near the bottom of the bridge of the furnace, and fitting into this opening a cast-iron tube, which bends upwards at the back of the bridge, and terminates in a somewhat contracted horizontal nozzle. Air, admitted under the ashpit by means of dampers placed at the front of the furnace, passes along the ash-pit, where it becomes heated, and then to the back of the bridge, where it mixes with the smoke and gases and assists combustion.—F. S. K.

Certain Improvements in the Cages of Hydro-Extractors. J. W. Collins and A. Kaye, Marsden. Eng. Pat. 2595, February 10, 1892.

THE patentees propose to make the cages of perforated sheet iron or of wire and cover them with a porcelain enamel.

—O. H.

New or Improved Process and Apparatus for Concreting Sugar or Crystallising Saline or other Solutions. W. P. Thompson, Liverpool. From J. A. Morrell and W. R. Stringfellow, New Orleans, U.S.A. Eng. Pat. 8336, May 3, 1892.

THE process consists in blowing compressed air through a vertical column of the saccharine or saline solution kept in violent agitation by rapidly revolving blades, in order to "economically and quickly convert the solution into a solid crystalline mass without boiling."—O. H.

Improvements relating to Refrigerating Apparatus. H. E. Newton, London. From W. Alsop and W. Blackall, Newcastle, N.S.W. Eng. Pat. 11,250, June 15, 1892.

IN order to dry the compressed air in cold air refrigerating apparatus more efficiently than is usually done by the ordinary coolers, and diminish the amount of snow which is deposited in the expansion chambers and passages, the air, after compression and passage through the coolers, enters a series of tubes so placed that the expanded air, on its way from the expansion chamber to the refrigerating chamber, impinges upon the exterior of the tubes and deposits its moisture upon them. The tubes, being slightly heated by compressed air passing through them, the adherence of the snow or ice is prevented, and the latter melt and drain away. The compressed air, as it passes through the tubes, parts with so much of its heat in the liquefaction of the snow or ice which is deposited on or around the tubes, that it is considerably reduced in temperature (generally below 40° F.).—O. H.

Improvements in Apparatus for Evaporating, Concentrating and Distilling Liquids. W. J. Mirreles and D. Ballinghall, Glasgow. Eng. Pat. 11,296, June 16, 1892.

BY this invention the liquid which it is desired to concentrate, undergoes a preliminary concentration in a steam boiler, in which high-pressure steam is produced for driving a steam engine, and also for heating the liquor as it passes through a tubular or other heater on its way to the boiler.

A blow-off pipe is fitted to the bottom of the boiler to allow the liquor, when sufficiently concentrated, to pass into

a second vessel where the pressure is reduced. More water is here evaporated in consequence of this diminution of pressure, and the steam passes to the first vessel of a multiple effect evaporator. The liquor likewise passes into the evaporator and is then further concentrated by its own steam.—O. H.

Improvements in Apparatus for Distilling Sea Water
S. Smillie, Glasgow. Eng. Pat. 11,787, June 24, 1892.

THE chief feature of this invention is the use of a duplex steam-coil bolted to the removable bottom plate of the distilling vessel, while the top rings of the coils rest on stirrup brackets carried on vertical rods also bolted on the bottom plate.

Both the steam inlet and outlet are flanged to the bottom plate so as to leave "sufficient freedom for vibration of the coils on the admission of steam to ensure dislodgment of salt or scale adhering to them, frequent removal for cleaning being thus avoided."—O. H.

Apparatus for Regulating the Flow of Volatile Liquid in Refrigerating Machines. T. B. Lightfoot, London.
Eng. Pat. 14,047, August 3, 1892.

THIS improvement relates to apparatus under Eng. Pat. No. 7712 of 1892 for regulating the flow of volatile liquid from the condenser to the vaporiser of refrigerating machines, and consists of a cylindrical valve with one opening rotating in a chamber having several lateral outlets, each communicating with a separate vaporiser. On the rotation of the valve each vaporiser is successively put in communication with the condenser through the opening in the valve.

—J.

Improvements in Apparatus for Regulating the Admission of Air and Steam to Furnaces for the Prevention of Smoke. J. K. Broadbent, Salford. Eng. Pat. 15,095, August 22, 1892.

IN order to prevent the emission of black smoke from furnaces immediately after stoking, it is usual to admit air through suitable openings, and also to employ a jet of steam, or "steam-poker," to produce a more rapid current of air. In previous patents (Eng. Pat. 5,927 of 1887, and 19,983 of 1891), apparatus for automatically regulating the admission of air have been described; the present patent refers to the admission of steam to the "steam-poker," which is now regulated, simultaneously and automatically, in the same way as the air supply.—F. S. K.

Improvements in Aerators for Treating Liquids. R. Andrew, London. Eng. Pat. 15,448, August 27, 1892.

THE improved "aerator" described, consists of a cylindrical vessel for containing the liquid, having in its lower part a perforated coil connected with an external vertical pipe, to which a sieve or strainer is attached. On the top of the vessel a steam ejector is placed, and below the outlet to this a conical baffle-plate is suspended. Air, purified by passing through the strainer, is drawn by the ejector through the perforated coil and passes in a continuous stream through the liquid.—J. C. C.

II.—FUEL, GAS, AND LIGHT.

The Manufacture of Oil-Gas. J. B. Ball. Proc. of the Inst. C. E. 1891—1892, 110.

IN this paper the author describes the plant used in the manufacture of oil-gas at the Holloway works of the Great Northern Railway Company, giving the dimensions of the various buildings and apparatus.

Pintseh's system of gas making is employed and the works are designed to produce about 60,000 cub. ft. of gas per day; at present the average make is only 15,000—18,000 cub. ft.

The 10-in. D-retorts are made of 1-in. metal and are 6 ft. in length; they are worked in pairs and are kept as nearly as possible at a cherry-red heat. Each pair will make 300—400 cub. ft. of gas per hour and 600,000 to 700,000 cub. ft. of gas before they require to be renewed. Immediately before the gas enters the hydraulic main, a $\frac{3}{4}$ -in. iron pipe, provided with a stop-cock, is tapped in so that the colour of the gas may be seen, this being the practical test applied to ascertain the quality of the gas and whether the proper quantity of oil is being admitted. Another test for regulating the supply of oil is to drop a small quantity of the tar from the gas main upon a sheet of white paper; if too much oil is being admitted to the retort a greasy ring will be found round the spot of tar, but if the right quantity is being used no greasy ring will appear.

The furnaces consume 160—180 lb. of coke for every 1,000 cub. ft. of gas produced. The oil used is a once-refined shale oil; it runs to the retorts from a galvanised iron cistern, of 50 gallons capacity, through a 1-in. iron pipe, at the end of which is fixed a gun-metal micrometer cock for regulating the supply. From this supply pipe the oil flows into a small funnel attached to a $\frac{3}{4}$ -in. siphon pipe, 12 in. deep, connected to the retort; it then falls on to a loose tray, preferably made of steel, and is instantly converted into a dense brown vapour.

The gas issuing from the retorts passes to the hydraulic main, then through air condensers, washers, and purifiers, into the meters and gas-holders. The purifiers contain a mixture of 2 parts of slaked lime to 1 part of sawdust, placed on wicker trays, and are recharged every week.

The cylindrical steel store-holders are 17 ft. 6 in. in length and 4 ft. 3 in. in diameter; they are tested by hydraulic power to 300 lb. per sq. in. and are provided with a pressure gauge registering up to 200 lb. per sq. in. The gas is forced into the store-holders through a 1-in. extra strong lead pipe by compressing engines; each holder is provided with a cock at the bottom for drawing off the condensed hydrocarbon, of which about a gallon is obtained from every 1,000 cub. ft. of compressed gas.

There are six men engaged at the works and the total cost of buildings and machinery amounted to 11,740*l*.

—F. S. K.

Probable Presence of Iron Carbonyl in Illuminating Gas.
Guntz. Bull. Soc. Chim. 1892, 7—8, 281—282.

IT was noticed that the lamp glasses of gas burners at Nancy, when used for a moderately long time, e.g., 40 to 100 hours without being cleaned, became covered with patches which, at first white, ultimately became red, and were found on analysis to consist of oxide of iron. Similar deposits have been observed on porcelain caps placed over gas burners and on porcelain plates used in regenerative burners. The gas must therefore contain a volatile compound of iron. This becomes more probable having regard to the fact that coal-gas is commonly purified by a mixture of calcium sulphate, oxide of iron, and sawdust, which when it is saturated with sulphur is revived by the addition of iron turnings. The excess of iron is acted on by the carbon monoxide always present in coal-gas and iron carbonyl is formed in small quantity. This hypothesis is borne out by the fact that in a town on the outskirts of Nancy no ferruginous deposits of the kind described were perceptible until the local gas works began to use the iron purifier above mentioned. A few days after the alteration had been made, the lamp glasses became reddened from the deposition of iron oxide upon them.

—B. B.

The Manufacture of Electric Light Carbons at Nürnberg.
Rev. Ind. 23, 384.

REPORT carbon is the material used in the process except in the case of cored carbons, which is manufactured according to the process of Messrs. Siemens Bros., of Berlin. The first operation is to break up the carbon in a mill; the coarser pieces from this process are crushed in a mill with vertical stones, and the finer are passed through a roller mill. The carbon which has been again broken up is sieved to separate the coarse grains from the fine powder, and the former are passed through roller mills. The fine powder so obtained is moistened, and compressed into moulds by hydraulic pressure, and the carbons are then roasted at a very high temperature. In this process great loss occurs, which at present appears unpreventable. The remaining process is to point the carbons. The machines necessary for an installation and their prices are given.

—G. H. R.

Coal Dust Explosions at the Zückerode Colliery. Max Georgi. Jahrb. für das Berg- und Hüttenw. im Königreich Sachsen. 1891, 1: Proc. Inst. Civil Eng. 108, 77.

See under XXII., page 938.

Recent Investigations on the Calorific Value of Coals. Deutecom. Zeits. des Ver. deutsch. Ing. 1891, 1375; Proc. Inst. Civil Eng. 108, 40-44.

On the assumption that the heating power of coals could be determined directly from their elementary chemical composition, the following formula, due to Dulong, has generally been used, the number of calories per unit of fuel burnt being—*

$$8,080 C + 28,800 \left(H - \frac{O}{8} \right) + 2,500 S - 600 W;$$

or, using more exact determinations for hydrogen and sulphur—

$$8,080 C + 29,300 \left(H - \frac{O}{8} \right) + 2,240 S - 600 W.$$

The factor W represents the latent heat of vaporisation from water at the temperature of the air to steam at 100° C., the oxygen in the coal being considered as combined with hydrogen to form water, and only the disposable proportion of the latter to be useful for heating purposes.

This formula would be undoubtedly true if coal were actually a mixture of carbon, gaseous hydrogen, sulphur, and water; but it is not actually so, the ultimate composition being no indication of the combination existing in the fuel. In any case it is abundantly certain that the carbon is not to any great extent present in the free state.

The older form of calorimeters are very delicate pieces of apparatus, in which the quantity of sample experimented on varies from about 0.3 to at most 1 gm.; so that the most scrupulous care is required in order to obtain trustworthy results. This difficulty has been met by the establishment at the experimental station at Munich of a calorimeter of sufficient size to allow the use of several cwt. of fuel in one test. It has a combustion chamber surrounded with water, and the gases are carried through a series of cooling tubes, until their temperature is reduced to that of the surrounding atmosphere. This gives very concordant results.

The conclusion from a great number of different coals tried in the large experiments is that Dulong's formula is practically exact, the variations from the calculated and observed results being at most 2 or 3 per cent., and in a majority of instances about 1 per cent.

The average calorific value of pure coal, i.e., considered free from ash and water, is about 8,000 calories.

* C, H, S, and W representing the respective proportions of carbon, hydrogen, sulphur, and water in a unit of coal.

The loss of heat by evaporation of contained water, and by the heated ashes falling from the grate, is comparatively small. A coal containing a per cent. of pure coal (free from ash and water), b per cent. of ashes falling out at t_b° of temperature, and c per cent. of water leaving the fireplace as steam at temperature t_c° , develops per 100 kilos.—

$$8,000 a - 0.2 (b t_b^\circ) - [620 + 0.4750 (t_c^\circ - 100)] c \text{ calories,}$$

or for—

$$a = 80, b = 15, c = 5, t_b^\circ = 700^\circ, \text{ and } t_c^\circ = 250^\circ \\ (64,000 - 2,100 - 3,456) \text{ calories.}$$

The losses from these sources is therefore less than 1 per cent. of the total available quantity of heat.

The most considerable item of loss in heat is that carried off by the gases which depends upon their composition and temperature. If pure coal be mixed with air in quantity sufficient to give a gas with 21 per cent. of carbon dioxide, 1 kilo. requires 2.66 kilos. of oxygen, giving 3.666 kilos. or 1.865 cubic metre of carbon dioxide, which in the chimney gases will be associated with 8.798 kilos. or 701.5 cubic metres of nitrogen. The heating of these gases to t° C. requires $(3.66 \cdot 0.2164 + 8.798 \cdot 0.244) t = 2.93 t$ calories.

If the gases contain a per cent. less carbon dioxide than 21 per cent., unburnt air is drawn in over the quantity of which x per 100 of coal is, when—

$$a : (100 - a \frac{100}{21}) = 186.5 : x$$

$$x = \left(\frac{18,650}{a} - 888.1 \right) \text{ cubic metres} \\ = \left(\frac{18,650}{a} - 881.1 \right) \cdot 1.2937 \text{ kilos.}$$

To heat this to t° requires—

$$\left(\frac{18,650}{a} - 888.1 \right) 1.2937 \cdot 0.2377 \text{ calories,}$$

and the total heat carried off in the gases is—

$$293 t + \left(\frac{18,650}{a} - 888.1 \right) 1.2937 \cdot 0.2377 t \\ = \left(20 + \frac{5,721}{a} \right) t \text{ calories.}$$

From the above formula the following table has been calculated showing by how much per cent. the heating effect of the coal is diminished per 100° of temperature in the gases, when the proportion of carbon dioxide in the gases is reduced below the theoretical maximum of 21 per cent.

CO ₂ in Gases. Heat Reduction.		CO ₂ in Gases. Heat Reduction.	
Per Cent.	Per Cent.	Per Cent.	Per Cent.
1	71.76	9	8.20
2	34.00	10	7.40
3	24.09	11	6.75
4	18.12	12	6.17
5	14.55	13	5.75
6	12.16	14	5.35
7	10.44	15	5.01
8	9.19		

With the help of these figures it is easy to calculate what quantity of heat is required in the daily working of any industrial heating arrangement.

An interesting branch of the inquiry is the comparison of these figures with those obtained from the thermochemical data corresponding to the reactions going on in the furnace, an example of which is given in the production of salt-cake or sodium sulphate from salt and sulphuric acid in alkali-making as follows:—

a. Chemical reactions :—

	Calories.
2 NaCl + H ₂ SO ₄ = Na ₂ SO ₄ + 2 HCl, this requires, per equivalent 142 kilos., 15,719 calories, or per 100 kilos.,...	11,050
Separation of sulphuric acid from diluting water,	14,000

b. Alteration of state of aggregation :—

Evaporation of 20 kilos. of water	20 × 520 = 10,400
---	-------------------

c. Heating of final products :—

100 kilos. of sodium sulphate to 500°	500 × 100 × 0.232 = 11,600
50 kilos. of hydrochloric acid to 100°	400 × 50 × 0.1832 = 3,704
20 kilos. of water vapour to 100°	100 × 20 × 0.475 = 3,800
350 kilos. of air to 100°	400 × 350 × 0.2377 = 33,278
Total	87,832

In a similar manner the heat requirements for the following chemical operations have been computed :—

	Calories.
Conversion of 100 kilos. of crystallised magnesium chloride into magnesia, hydrochloric acid, and water	116,020
Conversion of 100 kilos. of salt-cake into black ash with coal and limestone	131,453
Production of 100 kilos. of lime from limestone	87,795
Conversion of 100 kilos. of water into steam at 5 atmospheres	62,065
Conversion of 100 kilos. of zinc blende into zinc oxide	52,505

The last of these operations is therefore attended with a development of heat.

Taking into account the temperature and proportion of carbon dioxide in the gases, the effect obtained from the combustion of 100 kilos. of coal in the furnaces used in

these operations may be determined for comparison with that actually obtained in practice, as seen in the following table :—

Furnace.	Working Value of 100 kilos. of Coal in Calories.	Coal required per 100 kilos. of Product.		Difference.
		By Thermo-Chemical Calculation.	In actual Practice.	
Steam boiler	$\left\{ \begin{array}{l} 500,000 \\ 550,000 \end{array} \right.$	$\left\{ \begin{array}{l} \text{Kilos. } 12.5 \\ \text{Kilos. } 11.4 \end{array} \right.$	12-15	0.5-2.5
Lime kiln	$\left\{ \begin{array}{l} 450,000 \\ 575,000 \end{array} \right.$	$\left\{ \begin{array}{l} 19.1 \\ 15.3 \end{array} \right.$	18-30-43	27-11-24
Salt-cake furnace ...	450,000	19.1	35	16
Magnesia furnace ...	450,000	25.8	90-100	64-74
Black-ash furnace ...	350,000	35.6	60	24.4
Zinc-blende calciner	350,000	8.2	18	26

Apart from conduction and small uncalculated losses, the greater part of these differences must be attributed to heat dispersed by radiation from the furnace. The importance of this factor for the different kinds of furnaces is computed as follows :—

Furnace.	Daily Charge or Yield.	Daily Consumption of Coal in Kilos.			Radiating Surface of Furnace.	Daily Radiation per Sq. Metre in Kilog. of Coal.
		Actual.	Computed.	Difference.		
Salt-cake	Kilos. 3,500 sulphate	1,225	668	557	Sq. Metres. 80	6.9
Magnesia	1,120 MgCl ₂	1,060	289	771	80	9.6
Black-ash	5,400 Na ₂ SO ₄	3,240*	1,922	1,318	80	16.5
Blende calciner	7,000 ZnO	1,260	— 574	1,834	120	15.3
Steam boiler, 8.3 fold evaporation	62,500 H ₂ O	7,500	7,125	375	245	1.5
Steam boiler, 6.6 fold evaporation	50,000 H ₂ O	7,500	6,250	1,250	245	5.1
Lime kiln, iron jacketed with gas firing	1,000 CaO	1,736	788	948	210	5.0
Lime kiln with short flue producer	3,700 CaO	1,160	729	431	100	4.3
Lime kiln, Dietzsch's form	20,000 CaO	4,500	3,060	1,440	550	2.5

* 60 per cent. of charge, 42 per cent. of which is burnt, and 18 per cent. mixed for reducing.

—W. S.

PATENTS.

The Utilisation of a certain Waste Oxide of Iron in the Purification of Sewage, and for similar Purposes. H. C. Sacré and H. Grimshaw, Manchester. Eng. Pat. 17,911, October 20, 1891.

See under XVIII., page 933.

Improvements in Apparatus for Carburetting Gas or Air. The Gas Economising and Improved Light Syndicate, Limited, and J. Love, Barking, Essex. Eng. Pat. 18,082, October 21, 1891.

The apparatus to which this patent refers is that described in a previous patent granted to Love (Eng. Pat. 14,031, 1889).

The improvements refer mainly to the carburettor which, instead of being flat-bottomed, is now made curved or hollow, and inclined to one end so as to form a well in which the heavy hydrocarbons will collect; from this well they are drawn off into a closed drum by means of an air-pump, which at the same time forces fresh liquid into the

carburettor from the supply tank. The lower chamber of the carburettor is provided with an overflow pipe which runs to the supply tank; valves for controlling the flow of gas or air, and locking gear for the various cocks or taps, constitute the other improvements.—F. S. K.

Improvements in Apparatus for Washing, Purifying, and Scrubbing Gas. J. C. Chandler, London. Eng. Pat. 7,708, April 23, 1892.

The apparatus described in this patent is a new form of washer. It consists of a vessel, divided into a number of water-tight compartments, in which are placed horizontal perforated plates; tubes are fixed in the perforations, and the lower ends of the tubes dip vertically close to the surface, or beneath the surface, of the water in the compartment, so that as the gas passes from one compartment to another it is caused to impinge on, or to bubble through the water or liquor. Each of the compartments is provided with man-holes so that the perforated plates and tubes can be easily

taken out; each compartment is further provided with overflow pipes, the water or liquor being caused to flow successively through all the compartments.—F. S. K.

Improvements in the Manufacture of Iron and in Fuel, or a Compound suitable therefor. W. A. Sugden, Keighley. From W. R. Sugden, Fall River, Wisconsin, U.S.A. Eng. Pat. 18,442, October 27, 1891.

FOR use in smelting, puddling, or melting iron, the patentee describes a fuel by the employment of which it is claimed that the resulting iron is much improved in quality, chiefly owing to its dephosphorisation.

The fuel is prepared by saturating 2–3 cwt. of slaked lime with creosote or some other suitable oil, and then mixing it with 8–9 cwt. of slack or fine coal. This mixture is then sprinkled with a mixture of 1 lb. of powdered oxide of manganese and one quart of methylated spirit, and the whole thoroughly mixed; fairly good results may, however, be obtained without the addition of oxide of manganese and methylated spirit. One part of the patent fuel is used with 4 parts of ordinary coal or coke.—F. S. K.

Improvements Relating to the Manufacture of Gas, and to Apparatus therefor. H. H. Lake, London. From W. H. Harris, Boston, U.S.A. Eng. Pat. 20,420, November 24, 1891.

THE object of this patent is to generate fuel gas from coal, steam, and air, and then to obtain illuminating gas by the addition of hydrocarbons. The two processes are carried out simultaneously in the usual manner and the gas is then passed through a continuous regenerating chamber, which is filled with balls of silicate of alumina or similar material. For the details of the process and a description of the apparatus the original must be consulted.—F. S. K.

Apparatus for Quenching Coke. T. R. Osbourn, Philadelphia, Penn., U.S.A. Eng. Pat. 4032, March 1, 1892.

A CLOSE chamber adapted for containing coke is constructed with double walls forming a compartment or jacket into which water is introduced. By this means the heat radiated from the coke raises the temperature of the water and generates steam. The steam is led through suitably arranged pipes and discharged into the coke receptacle. The water-jacket may be sub-divided into a series of separate compartments, in each of which a pre-determined quantity of water may be introduced, and each of which may be provided with a separate steam-pipe.—D. A. S.

Apparatus for the Manufacture of Coke. T. R. Osbourn, Philadelphia, Penn., U.S.A. Eng. Pat. 4033, March 1, 1892.

THIS is a coke oven of a beehive pattern in which the hearth is moveable and may be lowered at will. After coking, the hearth is lowered on to a truck and removed, so that the coke can be quenched in a separate receptacle. A special quenching device is also described. It consists of a box-like receptacle of sheet metal mounted on wheels, and is designed to receive the contents of one or any number of coke ovens. Spray pipes are arranged in it so as to distribute water over the mass of coke.

The portable bottom of the oven is raised or lowered by means of a jack mounted on wheels, and adapted to run upon ways extending to or across the top of the oven.—D. A. S.

Improvements in Magnesium Flash-Light Apparatus. H. J. Haddan, London. From E. Beste, Weimar, Germany. Eng. Pat. 5996, March 28, 1892.

THIS is a lamp or device for producing a magnesium flash light, in which the magnesium powder is fed to the charge chamber from a reservoir by means of a spirally fluted shaft, resembling a spiral drill, the forward end of which projects into the base of the powder reservoir. The revolution of the shaft causes the powder to be forwarded along the spiral groove and to fall out at a narrow slit, from

whence it is blown out and propelled through a flame by a blast of gas. This blast is obtained by drawing gas from the pipe by a special valve by use of a piston, which is drawn down by a piston-rod by the operator or by a motor, if the lamp is to act automatically. On releasing it the piston is forced upwards by a spring when the charge of gas passes into the powder chamber, carrying the powder therefrom into the flame.—D. A. S.

Improvements in the Method and Apparatus for Producing Magnesium Flash-light. N. Browne, London. From P. Wunsche, Dresden, Germany. Eng. Pat. 6269, March 31, 1892.

THE object of this invention is to ignite the magnesium powder by means of percussion caps, and so dispense with the use of a flame. Hitherto the ignition by this method has not always been successful. The inventor recommends the substitution for the blow of a hammer at present used, the prick of a needle to perforate the fulminating material. The ignition of the caps in this way ignites only a small portion at first, so that the combustion of the fulminant is comparatively slow, and may be communicated with certainty to the magnesium powder. The percussion cap to be used is placed on a flanged plate and some magnesium strewed beside and upon it. By means of a lever a needle, which is supported perpendicularly to the plate, is forced downwards when desired, thus pricking the cap, igniting it, and thus causing the combustion of the powder.—D. A. S.

Improved Process of and Apparatus for Making Heating- and Illuminating Gas. A. Noteman, Toledo, U.S.A. Eng. Pat. 12,716, July 11, 1892.

FOR the production of illuminating and heating gas from petroleum the following apparatus is employed:—The petroleum is run from a small tank or reservoir by means of a narrow tube provided with a stop-cock, into the lower limb of a U-shaped tube, which is placed nearly horizontally; the petroleum pipe passes some distance into the lower limb of the U-shaped tube, and, as the liquid issues from the pipe, it is partially volatilised by a current of hot air, which is caused by the combustion of a bat-wing flame, burning in a perforated cylindrical vessel, the top of which communicates with the end of the U-tube. The heavier portions of the petroleum flow through a vertical pipe inserted into the lowermost portion of the U-tube, into a reservoir, whilst the gas, hot air, and products of combustion from the bat-wing flame pass along the upper limb of the U-tube into a gas-holder.—F. S. K.

Improvements in Apparatus for the Production of Fuel Gas. J. M. Bailey, Washington, U.S.A. Eng. Pat. 13,339, July 21, 1892.

THIS apparatus for the production of fuel gas is a very simple form of carburettor containing crude petroleum and broken stone, shells, or similar material; it is divided by two incomplete partitions into three chambers, of which the centre one is the smallest. The centre chamber is provided with shelves which extend alternately from opposite sides nearly, but not quite, to the other side; the spaces between the shelves are completely filled with broken stone, &c., and the latter is moistened with crude petroleum whenever necessary. The two lateral chambers are only filled to about one-third or one-half with broken stone, which is then completely covered with crude petroleum. Air, preferably heated a little, is forced into the bottom of one lateral chamber, then over one of the incomplete partitions into the top of the centre chamber, and finally into the bottom of the other lateral chamber. The gas obtained in this way is stated to be so thoroughly carburetted that it will not condense at the ordinary temperature; it is highly inflammable and develops intense heat by its combustion.—F. S. K.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

PATENTS.

Improvements in and Relating to Retorts for Distilling Shale and like Minerals, and for Dealing with the resulting Products. R. Orr and R. MacKay, Sutherland, Lidlithgow. Eng. Pat. 15,552, September 14, 1891. (Second Edition.)

THE improvements consist in a new mode of intermittently discharging the burnt shale from the bottom of the retorts into a lower hopper chamber, from whence it is delivered through the door of a shoot or hopper to the removing and conveying hutches. Two moving organs or apparatus fitted within the lower delivery chamber are arranged so as to move towards each other to hold the shale material or other mineral "in vertical line up within the retort, but when released will permit the whole column of material to descend evenly and in a body by gravity within the retort until the desired quantity has been passed through the lower hopper chamber into the hutches." The patentees have carried this idea into practice. Instead of leading the whole of the oil and ammonia gases away together and thence to condensers, there may be only partial condensation, and the ammonia gases may be neutralised by direct contact with acid, or the mixed vapours may be passed through separators and acid saturators of suitable construction. Or shale from which the oil has been wholly or partially distilled may be passed into other retorts or heating chambers, and there subjected to further heat, and the resulting vapours passed through acid saturators to form salts of ammonium.—D. B.

Improvements in the Manufacture of Mineral Oil and Ammonia. W. Young, Lasswade, N.B. Eng. Pat. 1587, April 12, 1881. Amended August 10, 1892.

THIS invention has for its object improvements in the system of distilling shale or other similar substances for the production of oil and ammonia, and consists in destructively distilling the shale at two temperatures, in such a manner that the oil shall be liberated and distilled from the shale at a low uniform temperature, and the remaining nitrogen liberated at a much higher temperature as ammonia. This is accomplished by first distilling out the oils from the shale at a low temperature in one retort, and thereafter transferring the residue into a second retort heated to a considerably higher temperature; or the operation may be conducted in one long retort, so divided that the shale shall be distilled free of its oil at one end and the distillation for ammonia completed at the other end, steam being employed for liberating the ammonia in the hot end.—D. B.

IV.—COLOURING MATTERS AND DYES.

Amethylcamphonitroketone. M. P. Cazeneuve. Bull. Soc. Chim. [3] 7, 1892, 327—331. (Compare this Journal, 1892, 512.)

THE sodium derivative of amethylcamphonitroketone,

is prepared by heating the nitroketone with soda in molecular proportion at 100°, crystallises in dark red micaceous scales containing 2 mols. H_2O , dissolves in water and alcohol, and dehydrates when heated on platinum foil. The ethyl derivative is formed when the potassium compound is heated for an hour with excess of ethyl iodide at 130°. It is a yellow, uncrystallisable, syrupy liquid, insoluble in water,

but soluble in alcohol and ether. It decomposes on distillation, and explodes when sharply heated. The sodium ethyl-derivative, $\text{C}_9\text{H}_9\text{NaC}_2\text{H}_5\cdot\text{NO}_2\cdot\text{O}$, is a red amorphous powder formed by treating a toluene solution of the preceding compound with sodium. It is soluble in water, and the solution gradually decomposes in the cold. It is also decomposed by carbonic anhydride. The acetyl derivative is obtained by treating the dry potassium or sodium derivative with acetyl chloride at 110° or acetic anhydride at 150°. It crystallises from alcohol in yellow hexagonal tables, melts at 65°, and remains in superfusion at the ordinary temperature. It explodes when heated above 250°. A sodium-acetyl derivative is formed by treating a toluene solution of the preceding compound with sodium. This is a bright red substance, soluble in water and more freely in alcohol; the aqueous solution gradually decomposes on standing. In conclusion, the author considers that the reactions of amethylcamphonitroketone point to the presence in it of the grouping $\text{CNO}_2\cdot\text{CH}_2\cdot\text{CO}$.—S. B. A. A.

The Tinctorial Properties of Amethylcamphonitroketone and its Auxochrome Group. M. P. Cazeneuve. Bull. Soc. Chim. [3] 7, 1892, 331—332.

AMETHYLCAMPHONITROKETONE has already been described (this Journal, 1892, 512) as possessing a golden yellow colour and tinctorial properties. In dilute alcoholic solutions it dyes wool and silk directly. When boiled with ordinary water it decomposes the carbonate of lime present, yielding a solution of the colour of the alkaline bichromates, which dyes wool and silk on boiling. It retains its dyeing powers in presence of tartaric acid, but not in alkaline baths. It does not dye cotton directly, but the material is dyed after one mordanting with tannin.

The author points out that whilst amethylcamphonitroketone contains the chromophoric group NO_2 , none of the salt-forming groups OH , NH_2 , COOH , SO_3H (Witt's "auxochromic" groups), which generally determine the dyeing powers of a compound, is present, and suggests that the acilic methylene group in the grouping $\text{CNO}_2\cdot\text{CH}_2\cdot\text{CO}$ may have a similar influence.—S. B. A. A.

Is Magenta Poisonous? P. Cazeneuve. Monit. Scient. Aug. 1892, 557—560.

IT is stated that for upwards of 29 years a workman of the firm of Durand and Huguenin, of Basel, had sifted magenta, as made by Couper's process, without having suffered from any illness. He only observed great thirst, caused by the dust of the magenta. It was estimated that this man swallowed, in the form of dust, rosaniline hydrochloride in quantities of from 1 to 2 decigrams per diem. In view of this fact, it is pointed out that since 1 milligram of magenta can dye 1 kilo. of sugar pink, the hygienic expert need not fear the use of magenta for confectionery.

It is considered that the wine merchant who uses magenta in his wine is reprehensible as an adulterator, but not as a poisoner.—M. B.

Reactions of the Addition-Product from Sulphur Dioxide and Sodium Phenylate. Formation of "Rubbadin." C. Schall and J. Uhl. Ber. 25, 1892, 1875—1901.

IT was recently shown by Schall that the product of the action of sulphur dioxide on sodium phenylate is presumably unsymmetrical sodium phenyl sulphite of the formula $\text{NaSO}_2\cdot\text{OC}_6\text{H}_5$ (Ber. 25, 1892, 1490). This substance reacts with benzyl chloride and with carbonyl chloride in accordance with the following equations:—

When sodium phenyl sulphite is heated with iodoform at 180°, a product having the composition $\text{C}_{14}\text{H}_{12}\text{S}_2\text{O}$ is obtained, and on account of its colour the author has named

it "*Rubbadine*." It is a reddish-brown crystalline colouring matter, which dissolves readily in alcohol, acetic ether, phenol, and in caustic soda solution. It yields a *diacetyl derivative*, $C_{41}H_{30}S_4O_8(OC_2H_3)_2$, and this on bromination gives $C_{41}H_{28}Br_2S_4O_8(OC_2H_3)_2$. *Dimethylrubbadine*—

forms reddish-brown microscopic crystals, insoluble in caustic soda, readily soluble in chloroform, and moderately in acetic ether.

A *hexanitro-derivative*, $C_{41}H_{25}(NO_2)_6S_4O_8$, obtained by the action of concentrated nitric acid on rubbadine, is a red crystalline dyestuff soluble in caustic soda with reddish-yellow colouration; also in ethyl acetate and acetone. A *tetra-nitrodiamido-product*, $C_{41}H_{25}(NO_2)_4(NH_2)_2S_4O_8$, obtained on reducing the hexanitro-compound, forms a black powder soluble only in phenol and in caustic soda solution.

When rubbadine is heated at 200° in a sealed tube with dilute hydrochloric acid, it becomes decomposed in accordance with the following equation:—

The product $C_{32}H_{20}S_2O_8$ is a light brown crystalline substance extremely soluble in ethyl acetate and acetone, and yielding a dark red solution in caustic soda.

When rubbadine is fused with caustic soda, it yields *dihydroxydiphenylsulphoxide* $(HO.C_6H_4)_2SO$, together with some phenol, salicylic acid, and sulphur. Dihydroxydiphenylsulphoxide is a crystalline grey-yellow powder melting at 95.5° and is readily soluble in caustic soda, ether, alcohol, glacial acetic acid, ethyl acetate, acetone, and in amylalcohol. Its *diacetyl-derivative*, $(C_2H_3(C_2H_3O)SO)_2$, melts at 110.5° . Its *polymeride* $(C_{12}H_{10}SO_3)_2$, obtained by the action of dilute hydrochloric acid at 200° , is a reddish-brown dye readily soluble in solutions of the alkalis and their carbonates, also in alcohol and ethyl acetate.

In conclusion the authors discuss the theoretical bearings of the reactions which they have investigated, and they suggest the following formula as probably representing the constitution of rubbadine:—

Azonium-Bases. O. N. Witt and C. Schmidt. Ber. 25, 1892, 2003—2008.

In this paper the authors describe some reactions of ethoxyphenyl-naphthostilbazonium chloride (Ber. 25, 1892, 1013), the most interesting of which is the substitution of the ethoxyl by an amido-group, thus bringing about the conversion of an azonium base into a saffranine. This reaction is effected by heating the stilbazonium chloride with alcoholic ammonia for two or three hours at 120° . The saffranine base crystallises out on cooling, and forms thick garnet-red prisms. The product is dissolved in boiling very dilute acetic acid, and the solution precipitated by the addition of hydrochloric acid. The *hydrochloride*—

obtained, forms scarlet needles, having a green metallic lustre; it dissolves in water and alcohol to scarlet solutions, which exhibit a faint greenish-yellow fluorescence. Silk, wool, and cotton are dyed bright pink by it. Its platinum-chloride has the composition $2(C_{30}H_{22}N_3Cl)PtCl_4$.

The corresponding *paratoluidine compound*—

is obtained when the above stilbazonium chloride is heated with paratoluidine for 8—10 hours at 110° — 120° . It forms

rectangular plates, dissolves readily in alcohol, sparingly in water, and is insoluble in very dilute hydrochloric acid. It dyes cotton a beautiful reddish-violet colour.

When the stilbazonium chloride is heated in a dry tube it first melts, froths slightly, becomes suddenly deep blue-red, and solidifies on cooling to a crystalline mass. This melts above 300° and at a high temperature sublimes mostly unchanged. The product of this reaction possesses the general characters of Fischer and Hepp's rosindone, and is, in fact, *phenyl-naphthostilborosindone*—

its formation being represented thus:—

A better method of obtaining it is to boil the stilbazonium chloride with six times its weight of dimethylaniline. It crystallises in garnet-red needles, is insoluble in water and dissolves only very sparingly in alcohol; it dissolves readily in phenol with orange-yellow colour, whilst concentrated sulphuric acid yields a beautiful violet solution which becomes yellow on dilution. The rosindone is a feeble base. Its *hydrochloride*, $C_{30}H_{20}N_2O.HCl$, crystallises in orange-yellow needles and scales, but is readily dissociated by water or by a temperature of 100° . The rosindone and its sulphonic acid dye silk red.—A. K. M.

Schiff's Bases. W. v. Miller and J. Plöchl. Ber. 25, 1892, 2020—2071.

In their paper on aldehyde-green (Ber. 24, 1891, 1700), the authors expressed the view that this substance is formed by the addition of hydrogen sulphide to the group $>C:N$. As this group is common to Schiff's bases the authors have attempted to effect the addition of hydrogen sulphide to the simpler members of this class of substances which they have also submitted to a closer investigation. The bases derived from the aromatic aldehydes, and of the type $C_6H_5N:C.H.C_6H_5$, are mostly well characterised crystalline compounds, whilst of those derived from the fatty aldehydes few are well defined and crystallised. With regard to their molecular weights, Raoult's method indicated a triple formula for *anhydroformaldehydaniline* and double formulae for *anhydrovaleraldehydaniline* and *acetaldehydaniline*. Whilst, however, anhydroformaldehydaniline and anhydrovaleraldehydaniline behave as simple bases in their reactions, acetaldehydaniline and the corresponding propylaldehyde derivative are shown by their abnormal behaviour to be differently constituted. The latter yield acetyl-, benzoyl-, and nitroso-derivatives, and consequently contain an imido group. When acetaldehydaniline is heated with hydrochloric acid it readily breaks up into aniline and quinoline, whilst propylaldehydaniline similarly yields aniline and α -ethyl- β -methylquinoline. The most probable formulae for these two bases are accordingly—

Isobutylaldehydaniline can also be partially converted into a similar polymeride, but all the other bases yield polymerides possessing a tertiary character.

All these bases can be obtained in their simple form—as oils—but they polymerise on standing and yield mostly solid products.

Of the hydrazones and oximes, only those belonging to the fatty series react with hydrogen cyanide. An interesting method of obtaining nitriles of the simple (*i.e.*, unpolymerised) bases is to dissolve aniline (or other amine) in ether, add hydrogen cyanide and then drop in the aldehyde. In this way nitriles can readily be prepared which cannot be obtained by other methods. This reaction

is of special interest as the nitriles yield important acid amides and acids. By the action of hydrogen cyanide on anhydroformaldehydaniline and subsequent hydrolysis of the resulting nitrile, the authors readily obtained phenyl-amido-acetic acid, $C_6H_5.NH.CH_2.COOH$, and since the yield is quantitative the reaction is of importance in connection with the synthesis of indigo.—A. K. M.

PATENTS.

Improvements in the Manufacture of Colouring Matter. H. H. Lake, London. From F. Reverdin and Ch. de la Harpe, Geneva, Switzerland. Eng. Pat. 16,377, September 26, 1891.

By the action of the air on a solution of β -amido- α -naphthol sulphonic acid in presence of an alkaline carbonate, a colouring matter is produced suitable for wool-dyeing. The oxidation is more rapid if the solution be heated whilst a current of air is passed through it. A solution containing 3 kilos. of amido- α -naphthol sulphonic acid—

and 2.3 kilos. of calcined sodium carbonate in 50 litres of water is heated in an open vessel on the water-bath and well stirred. For the first three hours the water which evaporates is replaced and the solution is then evaporated to about 20 litres, when it is allowed to cool and the colouring matter separates out as a violet-black powder, which, after filtering off, is washed with cold water and dried. It dissolves in hot water and dyes mordanted or unmordanted wool from an acid bath, giving dark shades fast to light and fulling. The amido-naphthol sulphonic acid is prepared by reducing azo-colouring matters obtained from 1.4 α -naphthol sulphonic acid or else by reducing the nitroso-compound obtained from the same body or from the sulphonic acid of α -hydroxynaphthoic acid, in the latter case, the NOH group replacing the carboxyl group.—T. A. L.

Manufacture of Colouring Matters from Protocatechuic Acid and Phenols. O. Imray, London. From "The Farbwerke vormals Meister, Lucius, und Brüning," Höchst-am-Maine, Germany. Eng. Pat. 19,547, November 16, 1891.

By heating acetic acid with resorcinol or pyrogallol in presence of zinc chloride, the following ketones are produced: resacetophenone, $CH_3.CO.C_6H_5(OH)_3$, and gallacetophenone $CH_3.CO.C_6H_3(OH)_3$. By applying this reaction to two bodies which hitherto have not been employed industrially, protocatechuic acid and pyrocatechol, new products result yielding very valuable colouring matters. When 34 kilos. of protocatechuic acid, 32 kilos. of pyrocatechol and 50–100 kilos. of zinc chloride are heated to about 150° C. for several hours and the melt dissolved in hot water, a tetrahydroxydiphenyl ketone crystallises from the solution and may be purified by crystallisation from water. When pure it melts at 175° C. By substituting resorcinol for the pyrocatechol an isomeric tetra-hydroxydiphenyl ketone is produced, which melts at 93° C. A penta-hydroxydiphenyl ketone is formed in a like manner from protocatechuic acid and pyrogallol. All the hydroxy ketones derived in this way from protocatechuic acid can be employed for dyeing and printing chrome-mordanted cotton and wool and give shades said to be absolutely fast to fulling.—T. A. L.

V.—TEXTILES: COTTON, WOOL, SILK, Etc.

The Determination of Fibrous Materials in a Crude State. S. Gabriel. Zeits. f. Physiol. Chem. 16, 1892, 370.

See under XXIII., page 944.

Pita-Flax or Sisal-Hemp. Annal. Indust. Paris, July 24, 1892; Proc. Inst. Civil Eng. 110, iv. 63–65.

The plant from which pita-flax is obtained is a native of South America and the West Indies, but it has been naturalised and become almost indigenous to all countries bordering on the Mediterranean—Algeria, Egypt, Sicily, Spain, and Portugal—where it is much employed as a boundary hedge for roads and fields. It is a species of aloe with a fibrous root, a very short trunk, large fleshy leaves of a sea-green colour, with prickly edges and pointed ends, from 20 in. to 4 ft. in length. The leaves increase in size year after year, and usually at the age of 20 or 30 years, but sometimes as early as its eighth year, a tall shaft is thrown up, which in about the space of a fortnight grows to the height of from 23 to 28 ft., and produces a flower at the top, but this so exhausts the plant that the effort usually kills it.

It is chiefly in the West Indies and Mexico that it is cultivated for profit. With the exception of the outermost and innermost leaves, of which the first are too coarse and the latter too tender, the rest are cut as near to the root as possible, and on being scraped and beaten with wooden instruments produce a valuable fibre of great strength. That from the exterior leaves is used for cordage and mats, and from the intermediate leaves coarse cloths are made, and the inner leaves produce a fine quality of fibre from which delicate tissues are woven resembling fine linen. It is sometimes prepared in Spain of a sufficiently fine texture to be exported to Lyons for mixing with silk fabrics. The Mexican varieties of aloe, called in that country "Magney," produce not alone a fibre which in France is known as Tampico horse-hair, and in England as Mexican grass, pita-flax, or sisal-hemp, but also a favourite intoxicating beverage (pulque), somewhat resembling perry, which is largely consumed in that country.

Hitherto the recovery of the fibre has in almost all countries been a tedious operation performed by hand, but in Yucatan a considerable trade has been created during the last few years by the application of machinery worked by means of horses or steam. From 5,000 to 7,000 leaves are daily crushed and the fibre separated by means of a wheel fitted with metal blades which revolves in a circular pan, each thousand leaves yielding from 55 to 90 lbs. weight of dry flax, and in this way the Yucatan production has been raised to an average value of 200,000l. per annum. This system, however, is in some ways objectionable, for it occasions a great deal of waste and often injures the attending workmen.

Mr. Berthet, who is already well known as the inventor of useful machinery of a similar kind, has recently introduced a greatly improved machine which, described and illustrated in Vol. 9, p. 33, of the "Bulletin de la Soc. ind. de Rouen," consists of two parts. The leaves are first crushed between fluted rollers, and are then made to pass between a curved wooden support and a drum fitted with many blades. This drum in revolving tears away the pulp from the whole length of the leaves and lays bare the fibre, but the operation is again repeated, whereby the separation of the fibre is completed.

In his work on the "Fibrous Plants of India," Mr. Forbes Royle gives the result of many tests made by him in India of the comparative strength of pita-flax and other fibres. He found it to be 70 per cent. stronger than Russian flax, and also that it has greater resistance than cocoa-nut fibre; when wet it shrinks 25 per cent. less than ordinary hemp-rope. (See Colonial Reps. Annual, No. 44, Bahamas, paragraph 15.)—W. S.

PATENTS.

Improvement in the Treatment of Fibrous Plants for the purpose of obtaining Fibres therefrom. D. Stuart, London. Eng. Pat. 751, January 15, 1891.

ALOE, jute, pine-apple ramie, flax and kindred plants in their green state are crushed and steam and water are then injected through the mass, by which means the pulp is speedily released and the gums are absolutely removed.

—E. J. B.

Improved Process and Means for the Chemical Treatment of Ramie Fibre, Flax, or Hemp, in either a Green or Dried State. J. P. A. Blaye, Paris. Eng. Pat. 13,072, August 1, 1891.

THE process consists in treating the above-named fibres for from 15 to 35 minutes at 95° to 100° C. in a bath composed of water, 100 litres, slaked lime, 10 kilos., carbonate of soda, 2½ kilos., alum, 2 kilos. After such treatment the fibres are easily removed by hand.—E. J. B.

Improvements in the Manufacture of Bookbinders' Cloth. T. A. Sutton and W. H. Sutton, Salford. Eng. Pat. 13,148, August 4, 1891.

THE inventors take grey calico or other similar fabric and raise upon one or both sides a pile or nap. They then dye or pad on to the pile the desired colour and then proceed to stiffen, glaze, calender or otherwise finish, and if necessary emboss a pattern. By this means the cloth is more evenly dyed and gains in density and solidity.—E. J. B.

Improvements in the Manufacture of Floor Cloth and like Fabrics, and Machinery therefor. R. Scott and W. J. Beard, London. Eng. Pat. 17,081, October 7, 1891.

DESCRIBES a machine for the manufacture of linoleum or similar fabrics in which a continuous pattern in various colours runs through the piece. A strong canvas back covered with an adhesive or sticky substance travels intermittently over a heated table. During the periods of rest, the various coloured portions of linoleum material are stamped out above the table on to the cloth. For each separate colour there is a special stamp and a special die-plate which exactly correspond to the shape and size of those portions of the pattern that are to be of that particular colour. When the linoleum of one colour has been stamped out and fixed in position on the canvas, the drum carrying the stamps revolves bringing into work a new set of stamps or punches and a corresponding die-plate. When the pattern is complete, it may be by seven or eight colours,

the canvas moves on the length of the pattern and is ready to receive the next length. Finally, the whole passes out between rollers which firmly fix the segments of linoleum to the canvas back.—A. J. K.

Improvements in Apparatus for Gassing Silk and other Yarns. C. Ideson, Leeds. Eng. Pat. 17,562, October 14, 1891.

IN order to effect an economy in time, gas, and power, the inventor has devised a new finger bar for gassing frames. At a point somewhat less than half way from the delivery end, the bar is bent into horse-shoe form; the gas flame playing across the centre of the bend. The straight portions of the bar at each side of the bend are in alignment, and along these are arranged at intervals pot friction tubes working on steel spindles. Two of the latter are also placed on each side of the bend and form equilateral triangles with the end tubes of the rows. This triangular arrangement is an essential feature of the invention, since by threading in different ways it permits of the yarn being passed from one to eleven times through the flame according to requirements.—W. M. G.

Improvements relating to the Waterproofing of Canvas and other Materials, and to Apparatus therefor. L. Silverman, Bexley, and W. McLaren, London. Eng. Pat. 17,977, October 20, 1891.

THE material to be waterproofed is placed in a suitable vessel from which the air is partially exhausted. The paraffin wax or other waterproofing material is then introduced under pressure. When thoroughly impregnated the fabric is withdrawn and passed first through two hot rollers, then between two revolving brushes, and finally between two cold rollers.—A. J. K.

Improvements in Machinery for Washing and Scouring Wool and other Fibrous Materials. J. Petrie and J. Fielden, Rochdale. Eng. Pat. 18,384, October 26, 1891.

IN this apparatus the principle is adopted of causing the flow of liquid to carry the wool through the machine; but in order to secure the maximum effect the wool passes through much less quickly than the liquid, and the method of bringing about this retardation is a principal feature of the invention.

The machine is constructed mainly on the lines of the ordinary wool-scouring machine, being provided with a long trough with perforated false bottom, feed and delivery apparatus, squeezing rollers, &c. The novel features will be understood by reference to the diagram in which *a* is a

MACHINERY FOR WASHING AND SCOURING WOOL.

feeding brat, and *b* the scouring trough over which is placed a perforated pipe *c*, extending the whole width of the trough. A continuous spray of scouring liquor from this serves to saturate the wool and also to feed the scouring trough. The revolving cylinder *d* depresses the wool

below the surface of the liquor, after which it is carried forward by the latter until it comes into contact with the retarding arrangement *j, j'*. This consists of several (two in the diagram) series of parallel bars placed horizontally to the apparatus, and spaced so as to allow the overlapping

ends of each series to fork into each other. By means of suitable mechanism each series of bars is alternately lifted out of, and depressed beneath the stream of liquid, squeezing the wool sufficiently to stop or retard its movement when in the latter position; but to prevent undue pressure, springs *r r* are inserted. The drum *y* at the delivery end of the machine serves to express a great portion of the liquor which flows through a perforated plate placed beneath the drum. The circulation of the liquid is brought about by a pump or injector.—W. M. G.

Improvements in the Treatment of Paper, Linen, and other Textile Fabrics applicable to the Manufacture of Show-Bills, Show-Cards, Posters, Tablets, Wall Decorations, and other Purposes. F. G. Annison, London. Eng. Pat. 19,710, November 13, 1891.

TEXTILE fabrics in long or short lengths are, by a special machine, which is fully described with reference to drawings, impregnated with an opaque or white solution of xylonite, celluloid, or ivoryine, and then passed through a heated chamber to remove alcohol and camphor. The fabric can then be printed in the usual manner, and is finally glazed or varnished.—A. J. K.

Improvements in the Treatment of Rhea, and in Apparatus therefor. E. Viarengo, Turin, and E. Casper, London. Eng. Pat. 20,610, November 26, 1891.

THE roots and tops are cut off the stems of the China grass, and the stalks sorted into three grades, thick, medium, and thin: for separate treatment. The stalks are immersed in water and boiled until the outer bark can be readily peeled off, after which the stems are placed in a closed vessel and boiled for about two hours under a pressure of at least 75 lb. in the following solution: water, 50 kilos.; soda, 1 kilo.; unpurified oleine, 500 grms. This removes all extraneous matters, including the gum. After thoroughly washing by means of a spray of water, the thoroughly-cleansed fibre is dipped in water containing 1 per cent. glycerin and 3 per cent. sodium carbonate, and dried in the open air.—W. M. G.

An Improved Hygienic Fabric, Tissue, or Material. J. Nyssen, Paris. Eng. Pat. 21,455, December 8, 1891.

AN electric fabric is produced, which is very hygienic, by mixing a material capable of becoming electric, such as cats' hair, with wool or other material.—E. J. B.

An Improved Shower-Proof Fabric. E. Briggs, Bradford. Eng. Pat. 3067, February 17, 1892.

THE fabric is made of silk containing its natural gum, the spinning, weaving, and dyeing operations being so regulated as to retain this constituent.—E. J. B.

Improvements in or Relating to Apparatus or Machines for Breaking, Washing, or otherwise Treating Vegetable Fibres. W. P. Thompson, Manchester. From S. B. Allison, New Orleans, U.S.A. Eng. Pat. 14,528, August 11, 1892.

THE object of the invention is to provide a machine for treating wood fibres or leaves, such as pine-apple, bear grass, banana, or other plants, the whole machine consisting of "moss and fibre brake," hackle and washing machine, with pressure rollers adjusted by set screws, in combination with a series of scraping blades, which interlace by means of eccentrics.—A. J. K.

VI.—DYEING, CALICO PRINTING, PAPER-STAINING, AND BLEACHING.

The Weakening of the Fibre in Discharge Indigo Printing. A. Scheurer. *Lebne's Färb. Zeitung*, 1891—92, 355. (Compare this Journal, 1892, 33.)

Two samples of discharge printing paste having the following composition were experimented with. (A.):—Potassium bichromate, 40 grms.; potassium chromate, 160 grms.; dextrin thickening solution, 800 grms. (B.):—Potassium bichromate, 50 grms.; potassium chromate, 300 grms.; dextrin thickening solution, 650 grms. Dark blue dyed strips were used as in the former experiments (*loc. cit.*). The development was effected in the case of (A.) by a bath containing sulphuric acid and oxalic acid (50 grms. of each to 1 litre of water); whilst in that of (B.), glycerol (50 grms.) was also added to the bath. After this treatment the printed strips were boiled with a solution of sodium carbonate, and tested with the dynamometer:—

	Relative Strength of Fibre.
Vat-dyed fibre.....	100
Sample printed with (A.).....	65
" " (B.).....	64

These results prove von Niederhäusern's statement (*Färb. Zeit.* 15 Juni 1892) that the use of glycerol is superfluous when the strength of the printing paste is properly adjusted; but it by no means follows that the addition of a reducing agent to the developing bath is useless. In practice, however, the printing paste always contains more than the necessary quantity of chromate, and the addition of glycerol or of dextrin (10 grms. to the litre), to the oxalic acid bath, minimises the weakening of the fibre, as previously stated by the author (*loc. cit.*).—A. R. L.

The Tannins and Tanning Extracts and their Application in Dyeing Cotton. V. H. Soxhlet. *Lebne's Färb. Zeitung*, 1891—2, 352—356, 378—379. (Continued from this Journal, 1892, 744.)

PINE bark extract, in spite of its being the cheapest tanning material in Germany, has a more limited use in cotton dyeing than even oak wood extract. Extract of Hungarian galls ("*Knoppern*") can be used in many cases for bright shades; the tannin-antimony compound is comparatively faint-coloured. Hungarian galls can therefore be used as a substitute for gall-nuts (or gallotannic acid), but of course they contain less tannic acid, and the accompanying colouring matters are stronger. The extract of Hungarian galls reduced to 15° B. has a clear colour, and contains about 25 per cent. of tannin; it produces no harshness with cotton fibre.

Bearberry leaves (*folia urse ursi*) contain a considerable percentage of tannin (also some gallic acid), but scarcely any soluble colouring matter. The extract (15° B.) contains 12 per cent. of tannin. The tannin-antimony compound is pure white, and the iron compound a beautiful bright blue.

White sea-rose roots were formerly employed as a substitute for nut-galls.

Quebracho wood contains as much as 20 per cent. of quebracho tannic acid, together with an intensely red-coloured resin, which latter restricts its general application for dyeing. It would, however, pay to decolorise the extract, and also to use it in admixture with logwood extract, but for the fact that the colours produced with it assume a foxy tone. Hemlock extract contains even more tannin (at 30° B., 44 per cent.), than quebracho extract, and is used in Canada with black dyes for cotton; the goods, however, invariably exhibit a foxy tone. The so-called black dye preparation sold in America is largely made up of hemlock extract.

Divi-divi extract comes into the market in a concentration of 30° B.; the author found 47 per cent. of ellagitannic acid in a sample. The yellowish tint of the antimony compound precludes its application for bright and medium shades; it yields, however, with iron salts a very deep greyish-black colour, and it can with advantage be used with all dark coal-tar colours.

Extract of myrabolans will unquestionably supersede that of sumae and other poorer tanning materials. This raw material contains 45 per cent. of tannin, a certain quantity of fat, and but little colouring matter; it is therefore well adapted for tinctorial purposes. The author prepared an extract by extracting the crushed substance five times with distilled water, and evaporating the extract to 15° B. on the water-bath. The tannin-antimony compound was very similar to that from sumae, whilst the iron compound had a beautiful full colour. The more fiery and intense tint which is produced with red, violet, and green basic coal-tar dyes fixed with myrabolans, as compared with sumae, is generally ascribed to the fat which the former contains; in most large English dyeworks, myrabolans or the extract are employed with predilection.

Bablah pods yield an extract (15° B.) containing 18 per cent. of tannic acid and some gallic acid, together with colouring matters and resin. This material might, if purchased at a moderate price, take the place of sumae; its chief application is for greyish-brown colours. Valonia meal, containing as much as 42 per cent. of tannin, can be purchased at 40 mk. per 100 kilos.; it yields 87 per cent. of extract (15° B.), and is a cheaper material than sumae extract containing 14 per cent. of tannin.

Cajota bark, probably identical with *Ecorce de palétuvier* (Bull. Soc. ind. Ronen, 1880, 187), contains 27 per cent. of tannin, and yields an extract resembling quebracho and hemlock extracts.

Algarobella seed husks (Chili) contain 61 per cent. of tannin, and yield 43 per cent. of extract (30° B.); it is not an advantageous tanning material for blacks, and the colour of its tannin-antimony compound precludes its use with coal-tar colours.

The employment of gallotannic acid is to be recommended, but the cost is generally prohibitive. Next to it may be placed the various extracts in accordance with the amounts of tannin they contain, and their costs. Sumae extract, on account of its high price and comparatively low percentage of tannin, is to be placed last. All extracts should be bought with a guarantee of their percentage of tannin. No such guarantee can be given with the raw materials, as they are liable to undergo changes by weathering, &c., and the author is of opinion that they should not be purchased.

—A. R. L.

The Gilding and Silvering of Textiles. E. Odenheimer. *Lehne's Färb. Zeit.* 1891—2, 375—377.

Two methods are in use for gold and silver printing on textiles. The first consists in the employment of the metals in the form of leaf or powder. On account of the expense of metallic gold and silver, bronze powders have been used as substitutes for them, with, however, somewhat unsatisfactory results. The second method depends upon the precipitation of metallic gold or silver on the fibre, from a solution of a salt, by means of a reducing agent. Neither of the methods in their present forms can be said to give perfectly satisfactory results. The author then gives a historical sketch of the development of the second method. He finds that in order to precipitate gold and silver on the fibre in a lustrous form, it is necessary to employ a gaseous reducing agent. Sulphuretted hydrogen produces, on fibres moistened with a solution of a gold salt, a brown or silver grey metallic deposit, which loses its lustre on drying; sulphurous acid gives no better result. Exposure of a fabric moistened with gold salt to sunlight yields a brownish or violet colour, whilst solution of ferrous sulphate gives rise to a brown or grey colour. Hydrogen precipitates the gold in a lustrous form, but its action is slow. By far the best results are obtained with phosphoretted hydrogen.

Reduction by Means of Phosphoretted Hydrogen.—A slow and continuous current of phosphoretted hydrogen is evolved on gently heating red phosphorus and alcoholic potash, and by this method the spontaneous inflammability of the gas is avoided. It acts very quickly, a beautiful lustrous deposit of metallic gold being produced when a small quantity of the gas is passed into a closed vessel in which the fabric moistened with gold solution is suspended. The fabric at first assumes a green colour, having a metallic

shimmer, and then passes through bluish violet to red; it finally has the lustrous metallic appearance above described. If the fabric in the dry state is treated with the reducing agent, or is insufficiently impregnated with gold solution, the deposit is more or less red without metallic lustre, and gold purple is formed when phosphoretted hydrogen at a high temperature is made use of. After drying, the deposit on the fabric loses its lustre, a result due to unevenness of surface, but the lustre is to some extent restored by rolling. The smoother the surface of the fabric, the more easy is it to obtain a lustrous deposit. Silk is in this respect the best material. The porosity and unevenness of the fabric are therefore the chief difficulties in the way of obtaining the desired effect; these may be overcome, however, to a certain extent by previously rolling. It is, however, preferable, in the case of making gold designs, to print the fabric first with a dilute solution of albumen, and subsequently, after drying and steaming, with a thickened gold solution, prepared by adding to 50 cc. of gum Senegal solution 5 cc. of a 2 per cent. solution of sodium gold chloride and 2—3 cc. of glycerol (compare this *Journal*, 1892, 600). The moist fabric is then subjected to the action of phosphoretted hydrogen, whereby lustrous gold designs are produced which withstand brushing and rubbing, but cannot be washed.

Silver behaves similarly to gold on reduction, and gives rise to various colours. Yellow is produced when the fabric is moistened with a 0.04 per cent. solution of silver nitrate and warmed for some time in a glycerol bath or tannin solution. Lustrous deposits of metallic silver are produced in the same way as those of gold, and good results are obtained with a 0.02 per cent. solution of silver nitrate. When the silver solution is too dilute, a thin naecous metallic film is deposited. For printing designs, the following mixture is employed:—Silver nitrate (0.1 gm.), gum Senegal solution (50 grms.), and glycerol (2 grms.) For silvering the entire fabric, a 0.02 per cent. solution of silver nitrate is strong enough. After reduction the silvered fabric is passed between heated rollers for the purpose of burnishing.—A. R. L.

PATENTS.

Improvements in Machinery or Apparatus for Cleaning and Lustreing Dyed or Undyed Yarns of Silk, Cotton, or other Fibrous Substances. S. Fisher and A. Murgatroyd, Huddersfield. Eng. Pat. 18,878, November 2, 1891.

In the usual machines for the above purpose the yarn passes from the winding-off bobbins round the lustreing cones, and finally through two sets of niches to the winding-on bobbins. In order to wind the thread laterally, one set of niches is made to traverse backward and forward, which has the effect of putting much more strain on the thread at one period than at another, thus limiting the drag which can safely be applied to the yarn. The use of niches at all is objectionable, because they collect the fluff which is removed occasionally by the thread, causing an uneven yarn.

The object of the present invention is to overcome these defects by passing the yarn in an approximately straight line from the unwinding to the winding-on bobbins without contact with any eye or niche, thereby securing the entire available amount of friction for the purpose of lustreing. A rotating brush removes the fluff.—W. M. G.

Improvements in Machines for Printing Fabrics. J. Wood, Ramsbottom. Eng. Pat. 19,174, November 6, 1891.

In some cases it is desirable that the cylinders of printing machines should be capable of horizontal adjustment, especially in duplicate machines, where both sides of the fabric are printed upon. The inventor proposes to arrange matters so that this can be brought about as follows:—The bearing blocks of the cylinders are fitted to slide horizontally, in planed ways, in carriages which are made to slide vertically, and are capable of being raised or lowered as occasion requires.—W. P. D.

Improvements in or Relating to the Dyeing of Silk and other Fibres. J. Longmore and R. Williamson, London. Eng. Pat. 20,574, November 26, 1891.

THE dyeing of silk in the higher qualities has only been successfully practised after it has been spun into yaru. The inventors propose the following method for dyeing it in the sliver, either before or after it has been dressed or combed. The sliver is wrapped round a drum by means of a gill-box, and dyed in this form of a lap, by which means it is possible to handle the silk in the sliver state without damaging it.

After removing the laps from the drum they are placed on a length of wire gauze, which is then rolled up and tied. The sliver is then easily handled and dyed. The dyeing operation may be made continuous.—W. P. D.

Improvements in or Relating to Means or Apparatus for Dyeing Yarns, Piece-goods, and the like. S. Smithson, Heckmondwike. Eng. Pat. 14,101, August 4, 1892.

THE object of this invention is to keep the goods from coming in contact with the dyewoods, or other solid materials used in the process of dyeing. Also to prevent any of the waste dyewoods, &c. from entering the drains, and thus becoming a nuisance.

The dye tank is divided transversely into two or more compartments, one of which contains the goods. A smaller division holds the dye-wood, and the liquor can flow from one to the other, through perforations in the sides, which are, however, not large enough to allow the dye-wood to get through and come in contact with the goods. Similar arrangements are made to prevent the solid matter escaping down the drains, when the tank is run off. A winch is added for piece-goods dyeing.—W. P. D.

VII.—ACIDS, ALKALIS, AND SALTS.

Improvements in the Manufacture of Sulphuric Acid during 1891. A. Schertel. Chem. Ind. 1892, 165—170.

IN the above year a work of considerable magnitude has appeared, by Alfred Retter (this Journal, 1891, 364), offering singular interest from the fact that the results given refer to the working of a one-chamber system. The dimensions of this single chamber were 188 ft. × 27 ft. × 21 ft. high, equal to 105,850 cub. ft. capacity; the capacity of the Glover tower was 1,020 cub. ft., or 0.96 per cent. of the chamber space. The pyrites burners, made in six compartments, consumed 3—3.3 tons of pyrites per 24 hours. The gases were sampled—(1.) In the tunnel between the Glover tower and the chamber. (2.) At two points situated 4 ft. 11 in. from the front wall of the chamber, about 3 ft. 4 in. from the floor, and 3 ft. 4 in. from the top. (3.) 33 ft. from the front wall, near the bottom and top. (4.) 92 ft. from the front wall, near bottom and top. (5.) 158 ft. from the front wall, as before. (6.) In the down-draught from the Guy-Lussac tower. The sample tubes reached in each case to a depth of 5 ft. into the chamber.

Working under normal conditions (i.e., consuming 3 tons of pyrites and 132 lb. of nitre per day), there is a remarkably sudden decrease of sulphurous acid in the chamber gases. Even in rejecting the tests taken at point (2)—the same being situated in a dead corner, away from the gas supply—we find only a slight reaction taking place between points (2) and (3), and almost no reaction past the latter. It was further remarkable that any attempt to increase the output by charging more than the above quantity of pyrites resulted only in irregularities in the process and in increased consumption of nitre. The tests show further, that nitrous oxide disappears along with sulphurous acid, as already pointed out by Lunge and Naef.

In reducing the air but increasing the nitre, the reaction advances as far as the far end of the chamber, and sulphurous acid along with nitrous fumes escape from the Guy-Lussac. But the most curious fact is an increase of oxygen from the point at which the gases leave the Glover. In the chamber inlet there is a deficiency of 1.89 per cent. (volume) of oxygen to completely oxidise sulphurous acid into sulphuric acid. At test-hole 2 there is already an excess of 0.36 per cent. (volume) of oxygen, which increases to 1.16 per cent. at the 4th test-hole. It is peculiar, too, that the proportion between nitrous acid and nitrous oxide remains uniform all through, although a deficiency of oxygen would lead one to expect a strong reduction of nitrous acid.

Increasing the air leads to an increased escape of sulphurous acid from the Gay-Lussac tower, and in some cases the chamber process is likely to be continued there. The sulphurous acid causes evolution of nitrous acid, which escapes. Under the above conditions it is very difficult to regulate the supply of air and nitre, and the losses in the exit gases are occasionally 30 times in excess of the average loss.

The temperatures are not subjected to strong variations and high figures, such as Sorel recorded; these were not observed here.

The output of this chamber being so very low, the same was divided into two smaller chambers, measuring 121 ft. long (68,607 cub. ft.) and 60.7 ft. long (34,417 cub. ft.) respectively. A passage 6.2 ft. wide divided the two new chambers. The chamber space decreased thus by 3.3 per cent., but the surface increased by 2.8 per cent. As a result of the alteration, 4.2 tons of pyrites could be burnt in 24 hours (i.e., this means an increase of 40 per cent.), with a consumption of 4.4 nitre per 100 of sulphur. The gas tests taken show that the sulphurous acid, when entering the chamber, does not decrease as suddenly as was the case in the one-chamber system. It decreases only very slowly past the second sample hole, but rapidly, almost to zero, in the second chamber. The samples taken on the top and bottom differ to a greater extent than formerly. The temperatures are much higher after splitting the chamber than formerly, even when burning the same quantity of pyrites, a circumstance which cannot be explained yet. Nevertheless, although there is a considerable source of heat in the chambers, one cannot help being struck by the considerable difference in the temperatures in the Glover tower and chamber (about 45° C.). Lunge and Naef observed in Uetikon a slight increase of temperature; the same was the case at the Oker and at the Mulden works, whilst there was a considerable rise in the temperature at the Freiberg works. The knowledge of chamber space and chamber surface do not throw sufficient light on this matter, and it is evident that the temperatures in the chamber system are influenced by conditions which are not yet recognised.

The behaviour of nitrous acid to sulphuric acid has been subjected to further studies since it became probable that the sulphuric acid vapours floating in the atmosphere of the chamber combine with nitrous acid, and thus prevent a further formation of sulphuric acid. The tension of the nitrous acid of nitrous vitriol has been studied by Lunge, Zalcwiecki, and Marchlewski (this Journal, 1891, 364—366). The specific gravities of nitric acid of different strengths were ascertained by Lunge and Rey (this Journal, 1891, 543—546).

The estimation of nitrogen in nitrates is treated of by Fricke, Alberti, and Hempel and Ulsch. The method employed by the latter is specially adapted to substitute the usual indirect nitre determinations.

Among the patented processes, the following may be mentioned:—Lunge and Kosmann electrolyse a solution of zinc sulphite (obtained by passing sulphurous acid gas through a paste of roasted zinc ore) for the purpose of obtaining zinc and dilute sulphuric acid. G. Léon obtains fuming or anhydrous sulphuric acid by electrolysis concentrated sulphuric acid. Neuerburg proposes to concentrate sulphuric acid in a copper apparatus, which is lined with gold up to the point of contact with the sulphuric acid.—H. A.

PATENTS.

Improvements in the Apparatus for the Manufacture of Bleaching Powder (Chloride of Lime) or Similar Commodities. J. M. Milnes and A. Milnes, London. Eng. Pat. 15,833, September 18, 1891.

AN endless belt made of suitable material, preferably of asbestos cloth, is caused to travel through a series of chambers, and upon it is placed the material to be saturated. In the case of bleaching powder the material is lime, which is fed in at a hopper, and chlorine is admitted at the end near the hopper and drawn through the chamber to the other end of the series. Hanging from the roof of each chamber are a number of combs which turn the material over as it is carried along by the travelling belt, thus continually presenting fresh surfaces for absorption of the gas. Drawings of the plant are given.—H. S. P.

Improvements in or Connected with the Production of Monocarbonates from Bicarbonates of the Alkalis. F. H. Gossage, Widnes. Eng. Pat. 15,822, September 18, 1891.

THE bicarbonate of soda or potash is placed in a closed vessel or series of vessels in a wet or dry state, and hot gas or hot air is passed through it by means of pressure or suction, the temperature being such as to convert the bicarbonate into monocarbonate. The gases that may be used are those that come from limekilns, in which cases they are enriched by the CO_2 expelled from the bicarbonate. When hot air is used it may be heated by passing through an interchanging apparatus subjected to the hot gases from the flues or furnaces of steam generators.—H. S. P.

Improvements in the Manufacture of Nitric Acid. R. E. Chatfield, Sewardstone, Essex. Eng. Pat. 16,512, September 29, 1891.

THE object of the invention is to obtain nitric acid free from sulphuric acid by distillation of nitrate of soda with sulphuric acid. To effect this a mixture of nitrate of soda is heated with large excess of sulphuric acid, preferably two equivalents to one of nitrate, at a temperature not exceeding 445°F . About 75 per cent. of the nitric acid distils over under 300°F ., and the remainder comes over, save a slight trace, at about 445°F . A temperature a few degrees higher removes the last trace. Owing to the low temperature the nitric acid is free from sulphuric acid. At the same time the resulting residue is liquid, and may be run off at any temperature above 350°F ., and may be used with an equivalent of salt to form muriatic acid and furnace salt-cake for the manufacture of glass, soda, &c.

—H. S. P.

Improvements in the Manufacture of Acid Sulphites. A. Boake and F. G. A. Roberts, Stratford, Essex. Eng. Pat. 16,647, October 1, 1891.

IN the ordinary process of manufacturing sulphites, sulphurous acid gas carries over from the plant in which it is generated minute particles of sulphur which are not removable by the ordinary means of washing, and this sulphur forms an unstable compound with the lime or other base, which even in minute quantities affects the value of the final product, especially if it be intended for the purpose of preserving beer. To obviate this the inventors first liquefy the sulphurous acid gas by pressure, and then allow it to gently boil off from the closed vessel in which it has been liquefied. The gas thus evolved carries over no sulphur, and is led through a suitable pipe into a solution of alkali or milk of lime, and the usual process of manufacture of acid sulphite solutions carried through.

—H. S. P.

Improvements in Apparatus for the Manufacture of Chlorine. P. de Wilde, A. Keyehler, Brussels, Belgium, and F. Hurter, Widnes. Eng. Pat. 17,659, October 15, 1891.

IN the De Wilde and Keyehler process for manufacturing chlorine (this Journal, 1890, 510), alternate currents of air and hydrochloric acid are passed through one heater at different temperatures. Considerable wear and tear is thus caused on the apparatus. This can be remedied to a certain extent by having separate heaters for the respective gases, but there still remains a certain wear and tear on the idle heater. The proposition is to work two heaters, one for air and one for hydrochloric acid, each connected with two cylinders, for containing the decomposing material, and with means for putting either heater in communication with each such cylinder alternately, and for drawing off the gases from each such cylinder conjointly. This is managed in such a way that air or hydrochloric acid can be turned on either decomposer; and whilst one of the decomposers produces weak chlorine, the other turns out strong chlorine, both uniting into a common main and giving a continuous stream of chlorine of uniform quality.—H. A.

An Improvement in the Manufacture of Bay Salt. A. MacNab, Cocanada, India. Eng. Pat. 10,851, June 8, 1892.

WHEN salt is produced by evaporation of sea-water there is always mixed with it other salts, chiefly magnesium chloride, which being of a deliquescent nature absorb moisture and render the salt damp. The invention consists in removing this impurity by placing the damp salt in the drum of a centrifugal machine having its outer wall of perforated metal or wire gauze, which may be lined internally with a porous fabric. The drum is then revolved and brine is poured into it, which is caused by the centrifugal motion to filter through the salt and to pass through the porous drum, carrying with it most of the magnesium chloride, which is more soluble than the salt. When the salt is very wet the addition of brine is unnecessary.—H. S. P.

Improvements in and Relating to the Manufacture of Crude Acetone. C. Lowe, Reddish. Eng. Pat. 12,660, July 9, 1892.

IT is proposed to submit to destructive distillation the acetates of strontium or magnesium instead of the acetates of potassium, sodium, calcium, or barium, hitherto employed. The resulting crude distillate is larger in quantity and of higher quality as regards the percentage of pure acetone present, and is also more free from empyreumatic or other by-products of decomposition. Any carbonic anhydride simultaneously evolved during the process of distillation, is separated by drawing or forcing the vapour of crude acetone over or through aqueous solutions of the alkalis or of their hydroxides, either in a pulverulent or semi-fluid state contained in covered vessels, whereby the carbonic anhydride is absorbed, afterwards condensing the vapour of crude acetone in an ordinary worm or surface condenser. Any crude acetone mechanically retained by the alkali is subsequently expelled therefrom by a current of steam or direct heat supplied in or to the vessels containing the absorbing agents. The patentee further proposes to utilise the by-products of the destructive distillation either after separation by fractional distillation from or while still mixed with the acetone of the crude acetone, obtained by employing them for the solution of copal or other suitable gums or resins for the preparation of varnishes, paints, enamels, cements, and the like.—D. B.

Improvements in the Manufacture of Vinegar and in Apparatus therefor. E. Küchenmeister, Zittau, Germany. Eng. Pat. 12,884, July 13, 1892.

THE apparatus consists of a wooden vat fitted with a cover which is hermetically closed and nearly full of the usual shavings.

The vinous liquid to be aceticated is discharged into the upper part of the vessel in a state of very fine division, which is produced by a current of air suitably applied, and which may be heated to any required temperature.

The excess of air passes off through a tube, by which it is first led through water to deprive it of any acetic acid or alcohol which might be carried away by it.

It is claimed that complete acetication is attained by one passage through the apparatus, so that a large quantity of liquid can be dealt with in a very short time.—A. L. S.

Improvements relating to the Manufacture of Sulphate of Ammonia. W. Malster, Catford. Eng. Pat. 13,208, July 19, 1892.

For the purpose of conveying ammonium sulphate from the bottom of the saturator on to an elevated drainer, a lead syphon is used, the vertical arm of which dips in the saturator, whilst the other arm delivers on the drainer. This end is closed with a metal plate valve hinged at the top. The syphon pipe, somewhat past the bend, is connected to a vacuum pump; each upward stroke of the pump fills the syphon with crystals, and each down stroke empties the arm leading to the drainer.—H. A.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

Oxygen in Glass Manufacture. Eng. and Mining J. 54, 413.

Recent experiments show that the introduction of pure oxygen gas in the crucible greatly facilitates the melting of glass; in fact, an economy in fuel of 30 per cent. is claimed.

The gas is contained in steel cylinders under a pressure of 120 atmospheres, the flow being maintained at a uniform pressure of $2\frac{1}{2}$ atmospheres by a regulator. The gas is introduced into the crucible through a platinum tube, which terminates in a spiral perforated on its under side. The gas is at first introduced very slowly, the quantity being gradually increased toward the last. The effect is to hasten the operation and promote the chemical combination of the different constituents. According to the figures given, 100 kilos. of glass require 600 litres of oxygen.

The glass made by the aid of oxygen is claimed by the workmen to be more easily workable, but the main advantages of the method are rapidity of fusion, which permits of an increased number of fusions per crucible, and in the rapid clearing of the melt, giving a glass free from air bubbles.—W. S.

PATENTS.

Improvements in the Manufacture of Cloth used for Press Sheets, Filtering Sheets and other similar Purposes. Sir E. Armitage and Sons, Lim., and P. Dunkerley, Pendleton. Eng. Pat. 10,643, June 23, 1891.

This invention relates to the strengthening at various places subjected to extra pressure the press sheets used in the manufacture of porcelain. The object is attained by using a double warp or weft, by doubling over and stitching down the cloth, or by sewing on an extra thickness.—E. J. B.

Improvements in and Applicable to Filter-Press Cloth, chiefly intended for Use in Filtering "Slip" for making Pottery's Clay. W. T. Lucas, Burslem. Eng. Pat. 6224, March 31, 1892.

These cloths are made in one piece, and are strengthened by a patch sewn on to the middle; a hole is made in the centre through which the slip-tap nozzle may be placed; the periphery of the hole is protected by two metallic collars which are placed on opposite sides of the cloth and clenched together.—J. C. C.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

PATENTS.

Improved Fire-Extinguishing and Fireproofing Compound. O. G. Hunkel, Besingo, Austria. Eng. Pat. 13,117, August 1, 1891.

A quick, reliable, and trustworthy fire-extinguishing compound may be obtained by mixing, and diluting to 22 gallons, solutions of about:—

	Lb.
Ammonium chloride in 1·4 gallons soft water.....	2·204
Burnt alum in 2·2 gallons soft water.....	0·770
Cryst. ammonium sulphate in 1·1 gallons soft water.....	0·140
Sodium chloride in 8·8 gallons soft water.....	4·408
Sodium bicarbonate in 1·1 gallons soft water.....	0·770
Sodium water-glass (liquid).....	9·920

—H. A.

Improvements in the Manufacture of Artificial Wood. P. A. H. Wehner, Dresden. Eng. Pat. 10,196, May 28, 1892.

ARTIFICIAL wood is prepared by mixing together sawdust, wood shavings, jute, flax, cotton, or waste animal matters with a solution of magnesium chloride and burnt and powdered magnesite.—E. J. B.

A New or Improved Heat-Insulating and Waterproof Material. E. Biernath, Charlottenberg, Germany. Eng. Pat. 13,702, July 22, 1892.

SEVENTY parts of infusorial earth, 10 parts of woollen waste, and 20 parts of "calf's hair" are worked into a thin paste with water, and if desired a colloid solution of any suitable kind. The composition is made into sheets about one-fiftieth of a millimetre in thickness, the sheets being cast on each other until a plate of about 4 millimetres in thickness is obtained, and the composite sheet subjected to a pressure of at least 12 atmospheres to free it from water, any remaining being driven out by heating. Ground asphaltum is mixed with a little "asphaltum oil," brought to its boiling point, and brushed on to the plates. Gravel or stone chippings about the size of barley grains are then strewn over their surface. The product is said to be suitable for lining silos and covering damp floors and walls.—B. B.

An Artificial Stone Composition. J. E. Keseling and C. Fuchs, New York, U.S.A. Eng. Pat. 15,147, August 23, 1892.

225 lb. of sand are mixed with half a gallon of a solution of asphaltum in turpentine, and with a mixture of 75 lb. of magnesia and 5 gallons of a solution of magnesium chloride, and 3—4 gallons of albumen dissolved in water at 150°—160° F., gradually poured in. The product is used as an artificial stone. The proportions may be varied.—B. B.

Improvements in or Relating to Decorative Artificial Stone for Forming Pavements and for other Purposes. W. F. Thomas, Dolgvan, Wales. Eng. Pat. 15,281, September 9, 1891.

THE process patented consists in forming letters or devices throughout the whole depth, from back to front, of artificial stones, by the insertion of suitable moulds and mixtures of ground stone with cement and the like, and the withdrawal of the moulds while the matrix is in a plastic state. The device may be used for the lettering of street names, tombstones and advertisements.—B. B.

X.—METALLURGY.

The Action of Carbon Monoxide upon Iron. Guntz.
Bull. Soc. Chim. **13**, 1892, 278—281.

THE action of carbon monoxide upon iron has been studied by many observers on account of its metallurgical importance. Stammer found that on passing carbon monoxide over oxide of iron heated to a temperature below the softening point of glass, a considerable quantity of carbon in a bulky state was obtained as well as metallic iron. Deville has recorded the fact that when iron is heated in carbon monoxide a deposit of carbon is formed upon the cooler parts, while those which are hotter are unaffected. Lowthian Bell has shown that when the oxides of iron, nickel, and cobalt are reduced by carbon monoxide, carbon is always set free. Some years later Grüner stated that pure iron does not decompose carbon monoxide free from carbon dioxide, but this was refuted by Schützenberger. Deville's observation is explained by the fact that the heat evolved by the reaction $\text{Fe} + \text{CO} = \text{FeO} + \text{C}$ decreases as the temperature rises and disappears or becomes negative at high temperatures. Failure to accept this view is due to the erroneous assumption that a substance stable at high temperatures is similarly resistant to chemical action. Thus carbon monoxide is very stable at high temperatures, but it is easily decomposed by oxidisable bodies as its heat of formation is low, 14.4 cal., a quantity of the same order of magnitude as that of mercuric oxide, viz., 15.5 cal. The reason why carbon monoxide is less vigorous an oxidant than mercuric oxide is that, on account of its stability, it is not dissociated when heated, and therefore needs the expenditure of work upon it to start its reducing action. If the metal to be oxidised is obtained in a sufficiently fine state of division, the reaction is much aided. Manganese, for example, burns easily in carbon monoxide when once the oxidation is started. It may be said that the oxidising action of carbon monoxide occurs at temperatures ranging between 100° and 400° C., and its reducing action from 300° C. to a red heat, the molecular state of the metal acted upon and its chemical activity determining the precise limits. Examples of both kinds of reaction are afforded by iron.

When carbon monoxide, at the ordinary temperature, is passed over iron, obtained by distilling an electrolytic iron amalgam in a vacuum at a temperature of about 250° C., iron carbonyl is formed in sufficient quantity to give a mirror-like ring of metallic iron, which is considerably more marked than that formed when iron reduced from the oxalate is used. On raising the temperature to 150—160° C. a part of the gas is absorbed with the formation of ferrous oxide and carbon, the presence of the latter becoming evident on dissolving the contents of the tube in acid. When heating is effected rapidly to about 300° C., carbon monoxide is at first absorbed almost completely, but afterwards, as the reaction diminishes, carbon dioxide is produced in small quantity, as a product of the reduction of oxide of iron by carbon monoxide. The reduction is never complete, as the action is reversible. Iron reduced from the oxalate or oxide gives the same reaction, but more feebly, its inertness increasing with the temperature at which it was originally reduced. Mechanically comminuted iron will behave similarly, though still less vigorously.

By these results certain phenomena in the smelting of iron may be explained. In one zone of the blast furnace spongy iron comes into contact with carbon monoxide yielding ferrous oxide and carbon; in another zone this ferrous oxide is reduced by carbon monoxide, giving spongy iron and carbon dioxide; finally, on reaching a zone of higher temperature, the finely-divided iron and carbon unite to form carburetted iron.—B. B.

Iron Carbonyl. Berthelot. Bull. Soc. Chim. **7—8**, 1892, 434—435.

METALLIC iron reduced from precipitated ferric oxide at the lowest possible temperature, or from ferrous oxalate by heating and subsequent completion of the reduction in hydrogen, is acted on by carbon monoxide at a temperature

of 45° C., the gas, after passing over the iron, containing sufficient iron to cause it to give a brighter flame than is usual. The flame has a characteristic spectrum, and deposits iron (partly oxidised) upon a piece of porcelain thrust into it. On passing the ferruginous gas through a narrow heated tube, a ring of iron, containing a little carbon, is deposited. Evidence is thus afforded of the existence of iron carbonyl (this Journal, 1891, 644), which helps to explain certain metallurgical phenomena such as the transference of carbon in the cementation process.—B. B.

Nickel Carbonyl. Berthelot. Bull. Soc. Chim. **13**, 1892, 431—434.

THE vapour tension of nickel carbonyl (boiling point 46° C.) at 16° C. (this Journal, 1890, 808), is about one-fourth of an atmosphere. A drop of the liquid allowed to evaporate spontaneously forms a certain quantity of crystals, which consist of the solidified substance, and speedily volatilise on continued exposure. It has no sensible tension of dissociation at the ordinary temperature, but in contact with air oxidises rapidly. The precise mechanism of oxidation varies according to the conditions under which it takes place. For example, when an inert gas, charged with the vapour of nickel carbonyl, is passed through a strongly heated tube, the products are metallic nickel and carbon monoxide, as observed by Mond and his colleagues (this Journal, 1892, 750). The same chemists have found that when nickel carbonyl is heated sharply to 70° C., at which point detonation takes place, the same bodies are formed. The author, however, has observed, that a certain amount of carbon dioxide and carbon is produced. He is of opinion that this reaction determines the occurrence of the detonation, as the equation $2 \text{CO} = \text{CO}_2 + \text{C}$ implies the evolution of 38.8 cal., i.e., 77.6 cal. for the 4 mols. of carbon monoxide in $\text{Ni}(\text{CO})_4$. The only assumption necessary to justify this view is that the heat of combination of Ni and CO is less than 77.6 cal.

The reactions of nickel carbonyl are generally those dependent upon the presence in it of nickel, but when they are induced gently and at a low temperature, bodies comparable to organo-metallic compounds are formed. The vapour of nickel carbonyl is not sensibly soluble in water or dilute acid or alkaline solutions or cuprous chloride. Hydrocarbons are its natural solvents; spirits of turpentine is specially suitable, and can be used for determining it. Explosion of a mixture of nickel carbonyl and oxygen can be effected by violent agitation over mercury as well as by direct ignition. Slow union takes place when such a mixture is kept in contact with a little water. In contact with strong sulphuric acid dry liquid nickel-carbonyl explodes after a short interval, but if in the form of vapour and diluted with nitrogen it is decomposed gradually, the theoretical quantity of carbon monoxide being liberated. Strong caustic potash has no perceptible action on nickel-carbonyl. Gaseous ammonia does not act immediately *per se*, but if a little oxygen be added fumes are produced, and if the action of oxygen be continued, a whitish deposit of complex composition and destroyed with charring on being heated, is gradually formed.

Sulphuretted hydrogen acts on nickel-carbonyl vapour, mixed with nitrogen in the cold, a black sulphide (of nickel) being precipitated. Phosphoretted hydrogen under similar conditions gives a brilliant black deposit. Nitric oxide gives rise to a very notable reaction. When nitric oxide is mixed with nickel-carbonyl vapour, diluted with nitrogen, or passed into the liquid itself, blue fumes, which fill the whole vessel, are produced. The formation of nickel carbonyl proves carbon monoxide to be capable of forming organo-metallic compounds similar to those derived from hydrocarbons, and is analogous to that of the salts of rhodizonic and croconic acids produced by the union of the condensed derivatives of carbon monoxide with an alkaline metal. Further study may elucidate the relationship. Nickel carbonyl serves as a fresh example of the tendency of carbon monoxide to form loose combinations and products of condensation, in virtue of its character as an unsaturated body.—B. B.

The Neuhausen Aluminium Factory. H. Wedding. Ber. d. Ver. z. Beförd. d. Gewerbeff. 1892, 125.

HÉROULT'S process, as employed by the Neuhausen "Aluminium-Industrie-Aktien-Gesellschaft," consists in fusing and decomposing pure alumina by an electric current. The vessel used for the reduction and fusing processes consists of an iron box lined with charcoal, which is connected by the copper wires *a* (see Figure) with the

HÉROULT'S PROCESS.

negative pole. The lower ends of a number of carbon-rods, serving as anode, are placed vertically in the box, as shown in the figure, the rods being held together by a frame *c*, which is connected with the wire *b*. At the commencement of the operation small pieces of copper are placed at the bottom of this vessel, and fused by means of the current. Then alumina is added, which is fused and decomposed by the current. The aluminium produced is run off at *d*, as shown in the figure, and cast into moulds. If aluminium bronze is required, copper and alumina must be added at the same time and in the necessary proportions. The working capacity of the factory is 1,000 kilos. of pure aluminium in 24 hours.—H. S.

Alloys of Iron and Chromium. Including a Report by F. Osmond. R. A. Hadfield. Iron and Steel Institute, Autumn Meeting, 1892.

This paper is a most exhaustive treatise on the above subject, commencing with a review of the early history and experiments, dealing with the various methods of producing ferro-chromium, its crystallisation, magnetic properties and uses, the soundness, hardness, mechanical tests, and applications of chrome steel, the electrical properties of chrome steel wire, and the laws of cooling and fusion of the alloys.

Extensive tables of figures are given, with the results in most cases plotted out into curves.

From a consideration of the methods of preparation it appears that the first step in the production of malleable iron-chromium alloys or chromium steel is to obtain reliable and uniform ferro-chromium. Attempts to obtain chromium steel by adding to, or melting with the bath under treatment chrome ore have practically failed, and until Baur had made a satisfactory ferro-chromium no success was achieved. The production of the latter by the crucible method being expensive it is applied only to making material containing high percentages, the blast furnace being employed in other cases. Alloys as high as 70 per cent. can now be bought and percentages as high as 80 or even 90 have been obtained experimentally. Chrome-iron ore is the most abundant source, and is found in Shetland, Uist and Fetlar; near Portsoy; at Var in France, Silesia, Bohemia, the Ural, New Caledonia, Maryland, Sydney, and California. It contains about 40 to 50 per cent. of the oxide. Large supplies also come from Brusa and Harmanjick, in Asia Minor. In California during the last seven years about 15,000 tons were raised, but the production is falling off owing to competition. The Tasmanian Iron and Charcoal Co., about 1872, produced in their blast furnaces iron containing

7 per cent. of chromium, but as the chromium converted all the carbon present into the combined form, and they could get nothing but a hard white pig-iron, of little use for foundry purposes, and which could not be puddled or converted into steel, they came to grief. Several hundred tons of the pig-iron were shipped to England, however, and as an alloy its use was beneficial for special purposes. The Ilfracombe (Tasmania) deposit is remarkable and on a very large scale. The ore is valued at the mines at 5s. per ton, and could probably be delivered in England for 15s. to 20s. per ton.

In 1869, Baur, produced ferro-chromium of 21 to 26 per cent. The ore was finely powdered, mixed with 6 to 8 per cent. pure anthracite or charcoal, and a certain quantity of flux containing calcium or sodium fluoride and lime or borax, and melted at a high temperature in plumbago crucibles. In 1875 Kern produced 74 per cent. ferro-chromium by melting Uralian chrome-iron ore with charcoal. Brustlein more recently prepared 84 per cent. alloy from specially prepared ore, which added greatly to the cost. 28 to 30 per cent. ferro-chromium has been sold at 25l. per ton, while 66 to 70 per cent. metal prepared in crucibles ranges from 90l. to 100l. per ton. The author found by experiments made 8 or 9 years ago, how comparatively easy it is to partially reduce chromium from the ore. About 40 lbs. grey hematite pig-iron was melted in a crucible and in an hour and a half 20 lb. of chrome ore was gradually stirred in. 4.37 per cent. chromium pig-iron, showing almost a spiegel fracture was formed. 15 lb. of chrome ore produced a similar effect, while, singularly, with 10 lb. the grey nature of the iron was unchanged, and no chromium was reduced.

In the blast furnace, in the latest and best practice, it is found easier to reduce chromium from its oxides than manganese, but to obtain high percentages of chromium, *e.g.*, 30 to 40 per cent., is much more difficult than that of 80 to 84 per cent. ferro-manganese, and requires much more fuel. The cause appears to be that ferro-chromium requires a considerably higher temperature for fusion, and through the practical necessity of allowing little or no chromic oxide to get into the slag, for it is found that even with so little as 5 per cent. the metal would not be fluid enough to flow from the furnace. It has been suggested that the presence of slag containing much oxide of chromium in contact with the fused metal tends to decarbonise or desilicise it and so to decrease its fusibility. If so, chromium behaves like iron rather than manganese. In any case large quantities of fuel must be used, and the reduction of the chromium oxide must be quite or nearly complete. In the case of ferro-manganese or spiegel more than 80 per cent. of the manganese is seldom reduced, but its oxide fluxes readily into the slag. Holgate found on reducing a mixture of iron and manganese as well as iron and chrome ore with carbon and flux in crucibles, all the iron and chromium were reduced in the one case, but only about two-thirds of the manganese in the other.

In practice more than three tons of coke per ton of ferro-chromium are required, much experience being necessary before high percentages can be obtained, and also very high temperatures of blast, *e.g.*, 1500° to 1600° F., to produce the necessary temperature for fusion. To form the slag, large quantities of alkaline carbonates, fluorspar, borax or lime are necessary. It has been stated that some of the ferro-chromium produced on the Continent is made by mixing a good quality of Bessemer slag with the chrome ore.

F. Osmond reports that "it appears that the chromium interferes with and impedes the crystallisation of the iron to a considerable extent, in this way reacting upon the structure:—(1) By the absence of Sorby's alternating lamellae. (2) By the absence or diminution of crystallised structure as shown by Brustlein in his publications on chromium steels." This action persists at all temperatures, but is more marked when not above about 1,000° than when at 1,200° C. or above. Small amounts under 0.5 per cent. are relatively more active than medium amounts; in the former case the chromium appears to be dissolved; dilute nitric acid dissolves the steel without leaving a residue. According as the amount of chromium increases, the compound

of chromium, iron, and carbon, only partially attacked by acid and possessing great hardness, appears to be formed. This hard compound may even be isolated in the form of globules.

General conclusions.—It appears to result from all the experiments that chromium may exist in at least three states, separately or simultaneously:—(1), as dissolved chromium; (2), as a compound of iron, chromium, and carbon in the form of isolated globules; (3), also the same condition in the form of a solidified solution. Pure chromium dissolved in pure iron seems to have no physico-chemical action, and would not have any other effect than that of interfering with the crystallisation of the iron, but this is extremely interesting as regards the mechanical properties. The triple compound as isolated globules imparts to the more malleable matrix a certain degree of hardness, combined with the relative plasticity of the matrix itself. The same compound when dissolved, owing to the introduction of carbon into the molecule, behaves like a body of small atomic volume, from which results the general or partial hardness of the whole, according to the proportions of chromium and carbon, and the more or less regular diffusion of the compound. The isolation of this compound presents great difficulties, as it is more or less attacked by all the reagents which have been tried. However that may be, the behaviour of chromium from the chemical point of view does not stand alone, for many bodies combine with iron, or with iron carbide, forming definite compounds which may be either dissolved in the mass of iron, or separated as free constituents, when the alloyed body is present in sufficiently large proportions. One of the peculiarities of chromium is its property of remaining free or combining with carbon, so passing from the class of bodies with high atomic volume to that of bodies with small atomic volume. It is difficult to foresee where these peculiarities will find new practical applications, but it seems evident that the scientific study of chromium steel, together with its mechanical properties, would introduce a greater degree of regularity and certainty in its manufacture.—A. W.

A New Process for the Purification of Iron and Steel from Sulphur. E. H. Saniter. Iron and Steel Institute, Autumn Meeting, 1892.

THE author in September 1890 commenced a series of experiments with the object of removing sulphur from iron. At first lime was tried but the effect was very irregular and imperfect. Remembering that many chlorides, *e.g.*, aluminium chloride, are easily reducible it occurred to him to try the action of calcium chloride, and he soon found that calcium chloride and lime, which he calls the "oxychloride," formed a very powerful desulphurising agent, being very rapid in its action and reducing the sulphur in the two experiments cited from 0.42 per cent. to a mere trace in half an hour. A mixture of 90 per cent. lime, and 10 per cent. calcium chloride was used which did not fuse but only softened.

The process on a larger scale is carried out as follows—calcium chloride and lime are mixed, and ground to a moderately fine powder in such proportion as to fuse readily at the temperature of the iron to be acted upon. About equal parts of each are required. The mixture is placed on the bottom of the ladle or receiver, and consolidated by heat or kept in position by any suitable means. At first a blow-pipe arrangement, using blast and furnace gas, may be used but when in continuous use the ladle retains sufficient heat to consolidate the mass. The iron, which may be drawn direct from the blast furnace, is run in, and the mixture, becoming melted, rises through the molten iron to the surface, carrying with it as sulphide of calcium nearly the whole of the sulphur. About 25 lb. each of lime and calcium chloride are sufficient for every ton of iron. Three tons of iron were treated at one time, and even when the first or coldest iron from the furnace was used, no "skull" was made, hence it may be concluded that larger masses would never "skull." The uniformity of the results was very marked as shown by a number of analyses cited, the results showing reductions from 0.220 per cent. sulphur to 0.060 per cent. from 0.300 to 0.060 per cent. and from 0.070

to 0.006 per cent. while the average of eight successive experiments with basic iron was from 0.077 per cent. to 0.022 per cent. The average elimination of sulphur was 73.6 per cent. and of silicon 35.8 per cent. The percentage composition of an average slag was calcium chloride 39.1, calcium sulphide 5.8, lime 38.6, and silica 12.9. Much of the calcium chloride in the slag can be washed out for further use. The ladle was of 4 tons capacity and lined with ordinary fire-bricks, but appliances are being constructed to deal with the whole product of the furnace as the metal is run. The plant is simple and inexpensive in character, consisting of ladles on wheels. The cost of materials is about 6d. per ton of iron treated, but against this cost may be set the cheaper production and enhanced price of the purer pig iron.

The process can be used for the purification of steel in the ladle after leaving the converter, and for the purification of hematite, basic, or common irons as they run from the blast furnace or cupola, producing an iron low in sulphur and silicon, suitable for direct steel-making. It is well established that in the "basic open hearth" process as ordinarily worked no sulphur is eliminated, and when ore containing much sulphur is used for feeding, sulphur is taken up, and the steel may contain even twice as much sulphur as did the scrap and pig iron originally used. The author states, however, that his process applied to the basic open hearth not only prevents increase but causes elimination of sulphur. For this to occur soon after melting a very basic slag, containing 50 to 60 per cent. of lime must be obtained, and suitable quantities of calcium chloride be added, when under these conditions irons and minerals containing sulphur may be used.

In 14 samples before treatment the amount of silicon varied from 0.04 to 0.65 per cent., the sulphur from 0.05 to 0.76 per cent., and the phosphorus from 0.05 to 3.5 per cent. After treatment the silicon (average 0.23 per cent.) was always reduced to traces, the sulphur from the average of 0.36 per cent. to an average of 0.045, and the average phosphorus from 2.3 per cent. to 0.038, the proportional reduction in the samples being very uniform. The steel has been sold for all purposes for which open-hearth steel is used, and found fully equal to that produced from the pure cast irons. The commonest iron scrap and ore may be used, and the use of common iron high in sulphur and low in silicon and carbon has the advantage that less steel scrap and a smaller quantity of ore for feeding are needed. The cost of calcium chloride is about 1s. per ton of ingots produced, while owing to the saving in cost of materials and in the quantities of scrap and ore there is really a saving of 4s. per ton. Neither hearths nor brickwork of furnaces and regenerators are affected by use of calcium chloride. This process is referred to by Stead in his paper (see the following abstract) on the same subject.—A. W.

The Elimination of Sulphur from Iron. J. E. Stead. The Iron and Steel Institute, Autumn Meeting, 1892.

THE author commenced his paper by a review of the present state of our knowledge of the occurrence of sulphur in the materials used in the smelting of iron ores, and the conditions under which it passes into the iron. In the coal the sulphur occurs in two forms:—(1.) as pyrites, the amount in that form being reduced by crushing the coal and washing out the pyrites before coking, and during the coking process; (2.) as sulphate of lime.

The low price of pig iron, and small profits thereon, prohibit the use of expensive methods of removing the sulphur from the ores. Magnetic ores can be separated from pyrites by crushing and the use of magnetic machines, but the powdered ore tends to choke the driving of the furnace and to choke the flues, whilst the increased blast pressure would increase the amount of dust carried into the flues. Calcining causes the elimination of sulphur as sulphur dioxide, but careful observation at Eston has shown that if carbonate of lime be present in the ore, the sulphur dioxide expels carbonic acid and sulphate of lime is formed, no sulphur being expelled, while the quantity is sometimes increased by retention of the sulphur dioxide from the coal used in calcining. There is no method of removing the

sulphates of lime and baryta from the ore when diffused through it.

The following general facts may be accepted as to the behaviour of sulphur in the blast furnace:—(1) When sufficient lime is present to combine with all the silica and sulphur and the temperature high, practically all the sulphur is retained by the slag; (2) other conditions being constant, as the temperature falls, to produce iron of closer texture more and more of the sulphur passes into the iron; (3) the more basic the slag, the smaller is the amount of sulphur in the iron; and (4) if manganese be charged in with the materials and the temperature be high enough, less sulphur will pass into the iron and more into the slag, this being constantly taken advantage of in producing basic iron in Cleveland and other districts. In the blast furnace when much below a red heat the sulphates of lime and baryta are not materially affected, but near or at a red heat they will be reduced to sulphides, and at a point in the furnace just hot enough to produce the lowest class of white iron capable of being fluid, we may assume that all the sulphur present in any form in the ores passes into the iron. As little coke is consumed before it comes in contact with the blast near the hearth, we may regard its sulphur as being locked up until then, and only when the coke is being burnt can the sulphur pass into the iron. The higher or lower the temperature, the greater or less will be the reducing power of the coke and the greater or less the distance above the tuyeres at which fluid cast iron is produced. During its passage downwards the fluid iron is exposed to higher and higher temperatures, encountering everywhere hot carbon, lime, and basic silicates. Hence it is easily understood how if the reducing power and basic material are sufficient, a high temperature favours the passage of the sulphur into the slag.

After discussing the older puddling processes, the author passes to the consideration of the sulphur in the acid steel-making processes. While Wedding states that sulphur, by the interaction of iron sulphide, silica, and carbon, is eliminated even to the extent of over 90 per cent. as sulphur dioxide, Bell, Howe, the author, and others state that no elimination takes place. In the ordinary English practice of melting in a cupola preparatory to blowing, the sulphur is often increased by 0.01 to 0.06 per cent., and the steel contains more sulphur than the original metal. Baker found that the sulphur at the end of a blow had been reduced from 0.107 per cent. to 0.093 per cent. At Seraing, with metal containing 3.75 per cent. Mn and 0.04 per cent. S, there was no change in the percentage of sulphur, the loss of that element being equal to the loss of metal in blowing. The author believes that the theory that during the first part of the blow the silica oxidises the sulphur must be abandoned, because there never is any free silica present, for it is well known that the magnetic or other oxides produced near the tuyeres are the main agents in removing silicon, which they do at their own expense with the formation of metallic iron and the immediate production of silicate of iron.

In the open-hearth acid process, Snelus, Hardisty, and the author agree that the sulphur is increased by absorption from the furnace gases, and any sulphur in the ore also passes into the metal. Willis found that 30 per cent. of the sulphur in sulphate of baryta contained in the ore passed into the metal. The siliceous slag always present in contact with the metal approximates in composition to that produced in burning out the silicon in the acid Bessemer process, and its having no action in eliminating sulphur in the open hearth completely demolishes the theory that it may have that effect in the converter.

In the basic Bessemer process nearly all observers agree that a notable amount of sulphur is removed. The estimates vary. From an examination of all the results it is ascertained that the larger the amount of sulphur present the greater generally is the amount of elimination, thus—

Per Cent.	Per Cent.
With 0.12 in the pig, the steel contains 0.15 or 0.4 per cent. less,	
" 0.397 "	" 0.085, 73 "
" 0.169 "	" 0.10, 37 "
" 0.09 "	" 0.06, 33 "
" 0.05 "	" 0.05, no change.

Harbord says that in the basic-hearth process 45 to 50 per cent. of sulphur is eliminated, while Hardisty estimates the average reduction at 33 per cent. It would appear that desulphurisation results from one or more of four causes:—(1) that the manganese added in the metal in passing out may carry some sulphur with it; (2) that the manganese reduced from the slag during dephosphorisation effects an elimination of sulphur; (3) that the calcareous slag in contact with the upper surface of the bath containing carbon may absorb sulphur; and (4) that some of the manganese added in the ferro-manganese does, undoubtedly, leave the bath again, carrying with it a small quantity of sulphur.

The author next considers the processes for the removal of sulphur from iron. Rollett's process consists "in melting pig iron and maintaining it at a very high temperature under a double action, slightly reducing and slightly oxidising, in the presence of a slag obtained by admixture of limestone or lime, iron ores, and fluorspar, in proportions depending on the quality of the pig or castings employed." He states that "the elimination is complete up to 99 per cent. or even more." The process is carried out in a jacketed or basic-lined cupola furnace, coke is the fuel, and a large excess of lime with some fluorspar is used, so that the silica in the slag is not more than 2 per cent. The author considers that probably the very calcareous slags employed are mainly responsible for the elimination.

Desulphurising with alkaline salts.—In Heaton's process fluid iron was poured upon nitrate of soda placed in a receiver and kept in place by a grating. Miller and Snelus found the sulphur was reduced to a trace, and the latter found a considerable amount of sulphate of soda in the slag. In Warner's process a mixture of ground limestone and soda-ash, and small quantities of other materials are used instead of nitrate of soda. Flames of what appears to be sodium burst out from the top of the vessel, and the slags contain some soluble sulphides. In two experiments cited the eliminations were 77 and 90 per cent. In Ball and Wingham's process potassium cyanide, sodium carbonate, or hydrate and metallic sodium were used, showing eliminations from 83 to 100 per cent. (this Journal, 1892, 751).

Massenez' process practically consists in mixing together in a suitable metal-mixer, pig iron, poor in manganese and high in sulphur, with iron containing more manganese and little sulphur, the manganese of the one combining with the sulphur of the other and the sulphide rising to the surface. Analyses of the metal from three furnaces showed respectively of manganese 1.72, 1.30, and 2.50 per cent., and of sulphur 0.15, 0.20, and 0.08 per cent., but after they were mixed the amount of manganese was 1.68 per cent., and sulphur 0.04 per cent. The author in his laboratory melted together 100 parts of ferro-manganese and a quantity of sulphide of iron in a plumbago crucible. After fusion and cooling, the scoria on the surface contained 56 per cent. of manganese, 28 per cent. of sulphur, and 1 per cent. of iron, proving conclusively that the reaction had taken place.

Ordinary foundry iron containing manganese, after melting in a cupola and pouring into large moulds in which it remains fluid for a considerable time, is often richer in sulphur and manganese in the upper portion than in the lower. An analysis by Ridsdale gave in the upper part 0.75 per cent. of sulphur and 1.35 per cent. of manganese, but in the lower only 0.112 per cent. of sulphur and 0.547 of manganese; but strangely the upper part was not white, hence it may be concluded that manganese and sulphur when combined and dissolved in the metal have not the same influence in preventing the carbon becoming graphitic as when in combination with the iron.

Saniter's process (see preceding abstract) is next dealt with by the author, who recently was present during the working of several charges at the Wigan steel works. The limestone added with the pig and scrap is more than in ordinary work, and as soon as the proper amount of calcium chloride is added when the charge is melted, lime and mine are thrown in. The following table illustrates the changes:

—	Calculated Analysis of the Charge.	7.20 after Melting	8.35 after adding CaCl ₂	10.10.	11.30.	Steel.
	Per Cent.	Per Ct.	Per Cent.	Per Ct.	Per Ct.	Per Ct.
Carbon ...	1.67	0.40	0.33	0.22	0.15	0.15
Silicon....	0.15	Trace	—	—	—	Trace
Sulphur ..	0.37	0.36	0.093	0.082	0.058	0.047
Phosphorus	1.67	1.25	1.106	0.343	0.065	0.056
Manganese	0.46	0.22	—	—	—	0.590

The slag, after adding calcium chloride, contained 10.81 per cent. of phosphoric acid and 1.25 per cent. of sulphur, and the steel slag 12.30 per cent. of the former and 0.65 per cent. of the latter. The sulphur removed in 1½ hour, after addition of calcium chloride, was 73 per cent., and the total sulphur removed was 87 per cent. Another charge showed reductions from 0.17 per cent. of sulphur, and 1.07 per cent. of phosphorus, to 0.055 per cent. and 0.048 per cent. respectively, a reduction of 67 per cent. in the amount of sulphur, but in this case there was a deficiency of lime.

A series of small experiments bearing on this process is then described. A small quantity of pig iron containing 4 per cent. of sulphur was heated to whiteness for two hours with lime alone, when all its sulphur was removed. With "the mixture," in one hour 97 per cent. was eliminated, while in two hours 100 per cent. was removed. Ninety-eight per cent. was removed by "washing" or pouring the molten metal into an excess of the mixture, the reduction in this case being from 1.86 to 0.04 per cent. of sulphur. An experiment to ascertain the action of molten iron on calcium chloride showed that oxide of iron formed on the surface of the former, and that the latter was decomposed to the extent that it contained over 14 per cent. of lime at the end of the experiment.

Taking all the facts into consideration, desulphurisation may be the result of one or more of the following reactions:—(1.) The chloride of lime in presence of free lime may be split up in contact with molten iron, the calcium in the "nascent" state may then combine with the sulphur in the iron, the chloride of iron in contact with free lime being converted into calcium chloride and iron oxide; (2) the extra lime in the slag may assist in the change; and (3) the sulphide of iron may simply be dissolved out by the oxychloride. When ordinary slag in the open-hearth process contains more than 0.25 per cent. of sulphur, some of the latter is liable to pass into the metal, and if sulphur is in the ore some of it also passes to the steel, but in this process the slag may contain 1.25 per cent. of sulphur, and yet continue to abstract sulphur from the charge.

In a supplementary paper the author describes many laboratory experiments undertaken to remove all doubt from certain disputed questions. He finds that both at low and high temperatures lime and sulphide of iron react, and that when the fused mixture is melted with silica, sulphide of iron is again formed. Pure iron will extract the sulphur from basic furnace slag if that slag is rendered acid with excess of silica. In smelting hematite with barium sulphate and an acid slag all the sulphur goes into the iron, but the same with a basic slag gives a metal containing only a small quantity.

Calcium chloride is incapable of absorbing sulphur *per se*, but it reacts to a certain extent with sulphide of iron, and in an iron containing 0.4 per cent. of sulphur it reduces it to less than 0.3 per cent. in half an hour. As the chloride on heating in air yields lime, however, it is pointed out that the change in the two latter cases might be due to lime. Strangely enough, calcium fluoride reduces the sulphur in the above iron to the same extent as the chloride when similarly employed.

The author states that it is certain that lime alone can remove the sulphur, which is always found afterwards as sulphide and not as sulphate of calcium. The lime is probably reduced to metallic calcium, which then decomposes the sulphide of iron. This is supported by the fact that the

percentage of carbon is reduced also, which action in some instances takes place in large excess of the proportion required by the calcium sulphide reaction. This, the author suggests, might be due to further oxidation by lime. He inclines to the conclusion that in the Saniter process lime is the acting agent, and that the calcium chloride acts as a vehicle by which the lime is brought into intimate contact with the molten metal.—A. W.

The Chemistry of the Cyanide Process. C. Butters and J. E. Clennell. Eng. and Mining J. 54, 1892, 391—417.

Solubility of Gold in Potassium Cyanide.—Faraday pointed out that gold leaf immersed in cyanide of potassium solution became so thin that it transmitted green light. Prince Bagnatton observed (J. pr. Chem. 31, 367) that the very finely-divided gold obtained by precipitating a solution of the chloride with ferrous sulphate may be dissolved by this reagent. Elsner showed, however (J. pr. Chem. 37, 333), that the presence of oxygen is required for the solution of the gold. A solution is obtained which, on evaporation, yields colourless octahedral crystals of the composition KAuCy_2 (auro-potassium cyanide) which may be looked on as a double cyanide of gold and potassium ($\text{KCy} \cdot \text{AuCy}$). The reaction which occurs may probably be represented by the following equation:—

There are two interesting points indicated by the above equation which may be remembered in conjunction with the application of potassium cyanide as a solvent for gold on a commercial scale.

1. That the quantity of cyanide theoretically necessary to dissolve a given weight of gold is infinitesimal in comparison with the weight actually required in practice. We see then that 130.04 parts by weight of potassium cyanide should be capable of dissolving 196.8 parts of gold, or, approximately, two parts of the cyanide should dissolve three parts of gold. The minimum actual consumption in treating free milling ore, assaying, let us say, 10 dwt. per ton, is about 40 parts by weight of cyanide for 1 part of gold. In the leaching tanks alone a pound of cyanide is generally consumed per ton of material treated.

2. That an extremely small quantity of oxygen is sufficient to bring about the solution of the gold, 15.96 parts being required for 396.6 parts of gold, or one part for nearly 25 parts of gold. The quantity present in a porous mass of tailings, to say nothing of that dissolved in the water used in making up the solution, would be considerably in excess of that actually required for the reaction.

Decomposition of the Cyanide.—How then does it happen that such an enormous consumption of cyanide occurs? In the first place there is the great instability of the simple cyanides. The atmospheric carbonic acid is accountable for a certain amount of decomposition, in which a constant evolution of hydrocyanic acid takes place according to the reaction $2 \text{KCyanide} + \text{CO}_2 + \text{H}_2\text{O} = 2 \text{HCyanide} + \text{K}_2\text{CO}_3$.

Then, again, we must consider the proneness to oxidation which the cyanides exhibit, and which, in fact, lies at the base of most of their technical applications. Potassium cyanide readily changes into cyanate, and ultimately into carbonate—

The presence of alkalis, which always occur in commercial cyanide, tends to induce loss by hydrolysis, which occurs mainly in the zinc boxes, and seems to be induced by this presence of the metal. In this reaction the alkali appears to determine a chemical change in which water plays a part, while the alkali itself is not in the least affected.

The hydrolysis of potassium cyanide, which undoubtedly occurs to a considerable extent when excess of alkali is present in the solution, or has been added to the tailings before treatment with cyanide, gives rise to ammonia and potassium formate.

The smell of hydrocyanic acid, generally noticeable in the neighbourhood of the cyanide tanks, is partly accounted for by the decomposition due to atmospheric carbonic acid. But there are grounds for supposing that in dilute solutions a

dissociation of the cyanide takes place, so that what we term a weak solution of potassium cyanide is in reality a mixed solution of potassium hydrate and hydrocyanic acid $\text{H}_2\text{O} + \text{KCy} = \text{HCy} + \text{KHO}$.

The truth of this theory is supported by the extraordinary fact that a distillation of hydrocyanic acid takes place when a current of a neutral gas (e.g., nitrogen) is passed through a cold dilute solution of cyanide. This being the case, it is evident that hydrocyanic acid, which is an extremely volatile body, must be constantly disengaged from all vessels in which weak cyanide solutions are freely exposed to the air.

Where the agitation or circulation systems are adopted, the consumption must be still greater, since these methods involve a constant exposure of fresh surfaces.

The tendency of the simple cyanides to form double salts with each other, or with other metallic compounds, must likewise be taken into account. Salts of iron, and to a lesser extent, salts of aluminium, magnesium, calcium, and the alkali-metals are liable to occur in tailings, especially such as have been long exposed to atmospheric influences.

We have said enough to show that, even under the most advantageous circumstances, an enormous waste of cyanide must take place. Some of these losses are doubtless preventable; the use of closed tanks and careful attention to the purity, both of the cyanide itself and of the water used for dissolving it, would reduce the extent of the decomposition in a very marked degree.

Action of Cyanide on Pyritic Material.—The surface ores of the celebrated "basket" formation consist almost exclusively of silica and oxide of iron. These occur in the form of rounded quartz pebbles, imbedded in a softer matrix highly charged with ferric oxide, which imparts its characteristic reddish tinge. The gold is found in this matrix associated with the oxide of iron, or sometimes in small scales on the surface of the pebbles. The pebbles themselves carry little or none. At a lower level this "free-milling" basket passes into an ore precisely similar in structure, but much harder, and containing the iron in the form of sulphide instead of oxide, which gives it a peculiar bluish tint.

There can be little doubt that the free-milling ores have been formed by gradual oxidation of the pyrites through the influence of air and moisture during a long period of time, and in fact we see this same change in progress whenever pyritic material has been exposed to the action of the atmosphere.

The pyritic ores likewise contain small quantities of arsenic, copper, and sometimes cobalt and nickel, but the amount of these foreign metals has so far been so small that they have not practically interfered in the cyanide treatment. It is noted as a fact observed in the treatment at the Robinson Chlorination Works of pyritic concentrates purchased from the various gold-mining companies, that copper and arsenic seem to occur in gradually increasing quantities with the increasing depth of the working. These elements may in the future be a source of serious trouble in the application of the cyanide process.

Suppose, now, that we attempt to treat a charge of partially oxidised pyritic tailings directly with cyanide solution. The moisture in the tailings has a distinct acid reaction, chiefly due to the presence of free sulphuric acid. This, of course, liberates hydrocyanic acid.

Ferrous sulphate (green vitriol) reacts upon the cyanide with formation of ferrous cyanide, a yellowish-red flocculent precipitate.

This, however, is under ordinary circumstances slowly converted into potassium ferrocyanide by the excess of cyanide present $\text{FeCy}_2 + 4 \text{KC}y = \text{K}_4\text{FeCy}_6$.

If sufficient acid be present, the ferrocyanide reacts upon an additional quantity of the ferrous salt, ultimately giving rise to Prussian blue.

The appearance of a blue colouration on the surface of the tailings, or in the solution, is a sure indication that acid iron salts are present, and that an enormous waste of cyanide has taken place.

Ferric salts, when present unmixed with any ferrous compounds, decompose cyanide solution with evolution of hydrocyanic acid, and precipitation of ferric hydrate, part

of which is in a finely-divided or possibly colloidal condition, and is with difficulty removed by filtration, as it chokes the pores of the filter.

A mixture of ferrous and ferric sulphates, such as is probably always present in partially oxidised pyritic tailings, causes the appearance of a blue colour on addition of cyanide, after the free alkali of the commercial product has been neutralised, Prussian blue being produced when the ferric salt is in excess, and Turnbull's blue when the ferrous salt is in excess.

Preparatory Treatment of Pyritic Material.—Before attempting to treat such ores or products with cyanide, it is therefore necessary to get rid of the free sulphuric acid and soluble iron compounds. This is generally done by giving a leaching with water until the liquid running off the tanks no longer shows a colouration with ammonium sulphide. After the treatment, however, there still remain the insoluble basic sulphates, which are gradually decomposed by water, and would act upon the cyanide solution. A washing is accordingly given with caustic soda or lime-water, which converts the basic salts into ferric hydrate, and sodium or calcium sulphates.

But the preliminary water-wash may be omitted with a laantage in cases where the quantity of free acid and iron salts is comparatively small. Lime, in the dry state, is sometimes mixed with the tailings before the cyanide treatment commences. When this method is adopted, the iron is precipitated as a mixture of ferrous and ferric hydrates.

After the washing with alkali is complete, the tanks are allowed to drain, and "strong cyanide solution" (about 6 per cent.) is pumped on. Even after this treatment, the consumption of cyanide, with moderately pyritic tailings which have been partially decomposed by exposure, is found to be four times that which occurs with free-milling material. The presence of a large excess of alkali in the solution brings about various secondary reactions which lead to a loss of cyanide, such as the hydrolysis, before alluded to, and a peculiar action in the zinc box, to be discussed later.

Lime, although slower in its action, is preferable to caustic soda as a neutralising agent, as it is equally effective in decomposing the iron salts, less active in bringing about secondary reactions on the cyanide, and also less energetic in attacking the zinc in the precipitating boxes.

Ferric hydrate does not appear to be acted upon by potassium cyanide, but ferrous hydrate, which is formed in the neutralisation of the iron salts by alkalis, reacts on the excess of cyanide, with formation of ferrocyanide of potassium $\text{Fe}(\text{OH})_2 + 6 \text{KC}y = \text{K}_4\text{FeCy}_6 + 2 \text{KOH}$.

Deposition of Gold from Cyanide Solutions.—Under certain conditions, such as the absence of sufficient oxygen in the solution, a partial precipitation of the previously dissolved gold appears to occur. If by any chance the solution should become acid, there is a decomposition of the double cyanide of gold and potassium, in which the gold is generally supposed to be thrown down as (insoluble) aurous cyanide, e.g. $\text{KAuCy}_2 + \text{HCl} = \text{KCl} + \text{HCy} + \text{AuCy}$.

In working on the circulation and transfer system, it is found that where pyritic material is under treatment, it is not safe to transfer a solution already rich in gold to a fresh lot of tailings, as the extensive decomposition of the solution which takes place may lead to a final loss of gold.

Selective Action of Cyanide.—It is claimed by the promoters of the McArthur-Forrest process, that in a mixture containing metallic gold, silver, copper, and base metals, cyanide of potassium exerts a selective action, dissolving first the gold, then the silver, and afterwards attacking the copper and base metals. The process, however, does not appear to have been successfully applied to ores, such as those met with in California and Australia, which contain considerable quantities of foreign metals. Ores containing sulphide of silver and sulphide of copper produce considerable decomposition of cyanide, the copper being partially dissolved as sub-sulphocyanide, the silver, however, remaining unattacked. In two experiments carried out by Mr. William Bettel, chief chemist of the Robinson Gold Mining Company, on ore from the Albert silver mine containing 30 oz. of silver and 10 per cent. of copper, it was

found that no extraction of silver occurred, this metal being present as sulphide.

Action of the Zinc Shavings on the Solution.—Theoretically a simple substitution of zinc for gold occurs in accordance with the following equation:—

Taking $\text{Zn} = 65.1$, $\text{Au} = 196.8$, it follows that 65.1 parts by weight of zinc should be sufficient to precipitate 393.6 parts of gold, or 1 lb. of zinc should precipitate about 6 lb. of gold. The actual consumption is about 1 lb. of zinc per ounce (Troy) of gold recovered. It is evident then that zinc is consumed in some other way than in mere substitution for gold.

During the passage of the solution through the zinc boxes a constant and vigorous evolution of hydrogen gas is observed. The outflowing liquid is found to possess a greater degree of alkalinity than it had on entering at the top of the box, and a smell of hydrocyanic acid, and sometimes of ammonia, is constantly observed in the neighbourhood of the zinc boxes. It is clear, then, that a decomposition of the potassium cyanide solution itself by the zinc is in progress, and this is not to be wondered at when we consider the powerful electro-chemical effect which must be produced by the contact of such a highly positive metal as zinc with a strongly negative metal such as gold. It is well known that the "copper-zinc couple" produced by immersing zinc in a solution of a copper salt decomposes water.

An analogous reaction of the gold-zinc couple accounts for the evolution of hydrogen mentioned—

The hydrate of zinc is at once dissolved in the excess of cyanide $\text{Zn}(\text{OH})_2 + 4 \text{KCy} = \text{K}_2\text{ZnCy}_4 + 2 \text{KOH}$, which reaction explains the increase in the alkalinity of the solution.

There are reasons for believing that the black deposit formed on the zinc shavings is an actual chemical compound of gold and zinc, which acts as the negative element in the electric couple, the undecomposed zinc forming the positive element.

When strong solutions of caustic soda have been used for neutralising the acid salts of the ore a white deposit is frequently observed on the zinc. The alkali first attacks the metal to form a zinc-sodium oxide—

This then reacts on the double cyanide of zinc and potassium always present in the solution, and precipitates the white insoluble simple cyanide of zinc—

This reaction is of some importance as affording one means by which the excessive accumulation of zinc in the solutions is avoided.

Affinity of Zinc for Cyanogen.—Potassium anrocyanide (KAnCy_2) appears to be one of the most stable of the salts of gold, but the reaction in the zinc boxes shows that the affinity of zinc together with potassium for cyanogen is greater than that of gold with potassium for the same radical. Hence a solution of potassium cyanide cannot dissolve gold which is in contact with zinc; neither can gold replace zinc in a solution of the double cyanide of zinc and potassium. So long as any zinc is present, therefore, we need not fear that the precipitated gold will redissolve in the excess of potassium cyanide flowing through the boxes.

It is evident also that the cyanogen contained in the double cyanide of zinc and potassium is not available for dissolving gold, and when a solution charged with zinc is employed in the treatment of a fresh lot of tailings it is only effective in so far as it contains a certain quantity of simple cyanide of potassium or other alkaline cyanide.

New Methods of Precipitation.—The cyanides of sodium and ammonium, and those of the alkaline-earth metals (calcium, barium, &c.), will dissolve gold, as well as potassium cyanide. Sodium cyanide is more difficult to

manufacture than the potassium compound, but a given weight of it should be more effective than the same weight of potassium cyanide, since 49 parts of the former are equivalent to 63 parts of the latter.

The advantage of Molloy's process and others which employ sodium or potassium amalgam are undoubted. The alkali metal is obtained by the electrolysis of the carbonate between electrodes of lead and mercury—

The sodium forms an amalgam with the mercury. Sodium amalgam may also be manufactured direct from its elements. It is claimed for this method of precipitation that the whole of the cyanogen is restored to a condition in which it is available for dissolving gold, as shown by the reaction $\text{Na} + \text{KAnCy}_2 = \text{Au} + \text{KCy} + \text{NaCy}$.

Composition of the Zinc Slimes.—Any base metals which happen to be in solution in the cyanide liquor are liable to be precipitated by the zinc along with the gold. Hence the "zinc slimes" are found to contain a certain percentage of copper as well as traces of arsenic and antimony. Moreover, any impurities in the zinc will also find their way into the slimes, as zinc will be dissolved by the cyanide in preference to any less oxidisable metals (e.g., tin and lead).

Silver is dissolved by cyanide and reprecipitated by zinc by a set of reactions precisely analogous to those of gold—

It has been observed that the proportion of silver to gold is greater in the "cyanide bullion" than in the gold from the batteries, and this is explained by supposing that the loss of silver in amalgamation is greater than that of gold.

Treatment of the Zinc Slimes.—The removal of the zinc is a troublesome operation and is only very partially carried out in smelting the dried slimes. The admixture of sand is made for the purpose of forming a fusible silicate of zinc. A portion of the zinc is volatilised, and burns at the mouth of the crucible with a greenish flame, producing the white oxide, ZnO , which is found incrusting the flues, and doubtless carries with it no inconsiderable quantity of gold and silver. The most promising method of treating these slimes appears to be that suggested by Mr. Bettel, of fluxing with acid sulphate of soda and fluorspar.

Attempts to remove the zinc prior to smelting have been only partially successful, as all such methods involve the filtration of a slimy mass which retains soluble salts with great tenacity.

The slags from the fusion of the zinc slimes contain a considerable amount of gold, some of which is in the form of round shots, and may be removed by pounding up the slag, passing through a coarse sieve, and "panning-off." The residue from the first fusion should always be fused again, with addition of lead, to form an alloy with the gold. The same lead-bars may be used for a number of successive fusions of the slag, and when sufficiently enriched, the gold may be recovered from them by cupellation.

Testing of Cyanide Solutions.—It is a matter of importance to determine exactly what strength of cyanide solution is used in treatment of tailings. The ordinary method of testing depends on the fact that silver cyanide is soluble in excess of potassium cyanide, with formation of a double cyanide of silver and potassium—

When silver nitrate solution is added drop by drop from a burette to a solution of cyanide, a white precipitate is formed, which quickly redissolves. At a certain stage the precipitate becomes permanent, when, in fact, the whole of the cyanide has been converted into the soluble silver salt, and an additional drop of silver nitrate produces a permanent precipitate of the insoluble simple cyanide of silver, $\text{KAgCy}_2 + \text{AgNO}_3 = \text{KNO}_3 + 2 \text{AgCy}$.

From these reactions 107.66 parts by weight of silver are equivalent to 130.04 parts of potassium cyanide. A

convenient standard silver solution is one of such a strength that every cc., added to 10 cc. of the solution to be tested, corresponds to 0.1 per cent. pure KCy .

This method gives good results when pure cyanide solutions are under examination, but when we come to test solutions containing zinc, it is difficult, if not impossible, to determine the end of the reaction. A white flocculent precipitate occurs at a certain stage, probably consisting of simple (insoluble) cyanide of zinc, formed by decomposition of the soluble double cyanide—

This precipitation occurs long before the whole amount of potassium cyanide has been converted into the soluble double salt of silver (KAgCy_2), for the solution, after the appearance of the flocculent precipitate, still gives the Prussian blue reaction with acidulated ferrous sulphate. A standard solution of iodine in potassium iodide may be used with great accuracy for determining the total amount of cyanogen in a solution, whether in combination with zinc or not, making use of the reaction—

The colour of the iodine is discharged so long as an excess of cyanide is present. The sharpness of the end reaction may be increased by adding a small quantity of starch to the solution under examination, which gives a permanent blue colour as soon as an excess of iodine has been added.

What is most needed, however, is a rapid method of determining the amount of cyanide available for dissolving gold, for, as was pointed out already, the cyanide in combination with zinc is not available for that purpose.

The method of testing solutions containing zinc for "available cyanide," which was introduced by Mr. Bettel at the Robinson General Mining Company's works, is as follows:—Two perfectly clean flasks of equal size are taken. To each of these is added a considerable bulk, say 50 cc. of the solution to be tested, and 50 cc. of water. The liquid in both flasks will probably appear slightly turbid, but the degree of turbidity will be the same in each. Standard silver nitrate solution is run into one flask until the slightest possible increase in turbidity is observed on comparison with the liquid in the other flask. This point is taken as indicating the conversion of the whole of the free potassium cyanide into the soluble silver salt, and, therefore, as determining the amount of available cyanide present in the solution.

The amount of gold in the solution is generally found by evaporating a known bulk with litharge, fluxing the residue, and cupelling the resulting lead button. Evaporation on lead foil may likewise be employed.

Poisonous Properties of Cyanide.—The men employed in the "clean-up" and in melting the slimes are subject to a peculiar eruption, especially on the arms, and complain of headache, giddiness, and general depression. Ferrocyanide of potassium has been recommended as a remedy for the eruption; it may be taken internally and also applied as a lotion. Considering the dangerous nature of the substance, it is remarkable how few fatal accidents have occurred through the use of cyanide on a large scale. In cases of poisoning, precipitated carbonate of iron, obtained by mixing solutions of sodium carbonate and ferrous sulphate, may be used as an antidote. This forms internally an insoluble blue compound with the cyanide.

Hydrocyanic acid acts directly on the nervous system, causing instant paralysis; hence any treatment which will excite the action of the nerves, such as application of cold water to the spine, inhalation of ammonia, &c., may be tried in cases of faintness produced by breathing the vapour of the acid.

The disposal of waste cyanide liquors is a matter for serious consideration. Solutions containing 0.1 or 0.2 per cent. of potassium cyanide must occasionally be discharged, and are likely to contaminate the water of the dams or streams which receive them to a dangerous extent. If some effective means of precipitating the zinc, or, better still, of dispensing with the use of zinc altogether could be

devised, there would never be any necessity for allowing cyanide liquors to leave the building (this Journal, 1891, 93—98).—W. S.

The Cyanide Process in South Africa. C. Butters and J. E. Clennell. *Eg. and Mining J.*, October 1892, 341—342, and October 15, 365—366.

The following is a description of the process as carried out by the Robinson Gold Mining Company:—

Solution of the Gold.—When the cyanide process was first introduced about two years ago, it was thought necessary to agitate the material under treatment with the cyanide solution. At the present day the "percolation" system is almost invariably adopted. The operation is carried out by the African Gold Recovery Company, who represented the patentees in South Africa, as follows:—The damp tailings, taken from the tailings pits, are charged into wooden vats of a capacity of 35 to 50 tons; these vats are usually square. The best works are now building circular tanks. Those at the Robinson works have a capacity of 75 tons; those now in use at the Langlaagte Estate have a capacity of 400 tons, and still larger vats are being constructed for the cyanide works at the New Primrose mine. The vats are filled to within a few inches of the top, and the surface of the tailings levelled. Cyanide solution of 0.6 to 0.8 per cent. strength is then allowed to flow into the tank until it is completely filled. The ore settles from 3 in. to 1 ft. below the rim of the tank (the amount of shrinkage depending on the depth of the vat). This solution is allowed to remain undisturbed, in contact with the ore, for 12 hours. Each vat is provided with a false bottom—usually a wooden framework covered with cocoanut matting. Below this is a layer of coarse sand and pebbles through which the solution percolates. An iron pipe communicates with the vat below the false bottom, and conveys the filtered solution to the "zinc boxes," where precipitation takes place.

The dilute cyanide solution does not attack a wooden vat, nor does it corrode the iron piping to any appreciable extent. As to wear and tear of apparatus the use of cyanide offers decided advantage over chlorine or chlorine water. Brass plungers and valves, such as are in use in ordinary pumps, are attacked, but not very rapidly. The pumps at the Robinson works were in use for four months with comparatively little wear, but iron is, of course, preferable for all pump fittings where cyanide solution is used. As the liquor is drawn off during the leaching process it is replaced by fresh solution. This operation is continued for a longer or shorter period, depending on the value of the tailings (about six to twelve hours).

At the end of this period, which is known as the "strong solution leaching," a weaker solution (containing 0.2 to 0.4 per cent. of cyanide) is turned on, and allowed to filter through the ore for about 8 to 10 hours. This "weak solution" is then drawn off through another zinc box. Finally, a quantity of water is run into the tank, more or less equivalent to the amount of moisture which the ore contained when the tank was filled. This last water-washing displaces the weak cyanide solution, so that the volume of cyanide solution in use remains unchanged. The "weak solution" is, in fact, the liquor which has previously passed through the zinc boxes into the receiving tanks or "sumps," and has been pumped again to the leaching tanks. The cyanide is usually contaminated with carbonaceous matter and iron, but contains 72—78 per cent. of pure potassium cyanide.

The actual amount of cyanide used is about half a ton of strong (0.6 to 0.8 per cent. solution) and half a ton of weak (0.2 to 0.4 per cent.) solution for every ton of ore treated. As the amount of cyanide actually entering into combination with gold and silver is almost infinitesimal in comparison with the quantity consumed in the different stages of the process, it will be obvious that there is still considerable scope for inventive genius in determining the conditions of economical working. When the final water-wash has been added, and has displaced the weak solution, the "exhausted tailings" or "residues" are discharged, usually by the somewhat tedious process of shovelling out over the side. A truck-line runs across the top, or by the

side of the tank to receive the discharged tailings, which are then removed and deposited outside the works. The tank is then ready for a fresh charge.

The "percolation system" has been modified in various ways.

One of the first difficulties in the application of this process arose when tailings were treated containing a small percentage of pyrites, which by exposure to the air had become partially converted into sulphate of iron and free sulphuric acid. The difficulty could be minimised by treating tailings direct from the battery, first with water and then with some alkaline solution, such as lime or caustic soda. At the Robinson works lime was found to be in every way preferable to the stronger alkali, as it is less active in inducing the decomposition of the cyanide solution in the tanks, and in attacking the zinc used in the subsequent precipitation. It was, moreover, found that 20 tons of solution sufficed to fill a tank holding the usual charge of 75 tons of tailings, covering the charge to a depth of 3 or 4 in. Instead of replacing this 20 tons of solution by fresh cyanide, the solution filtering through was continually pumped back again into the same tank for about 36 hours, and then passed through the zinc box. The extraction of gold by this circulation system was equal to that obtained by the ordinary method, and the consumption of cyanide was much less, since a much smaller quantity of solution was exposed to the action of the zinc. A further modification suggested itself, namely, the transference of the solution charged with gold, from one tank to a second and third, in order that it might take up an additional quantity of gold from fresh tailings, before passing into the zinc boxes. The advantages of this method are that the solutions from which the precipitate is obtained are much richer in gold, giving a cleaner deposit on the zinc, with much less consumption of cyanide.

The usual practice, as we have pointed out, is to dissolve the cyanide in a special tank set apart for that purpose. At the Robinson works the strength of the cyanide solution is kept up by adding cyanide in lumps, dissolving it under the steam from the pump. By this method a cyanide solution of required strength is formed in the leaching tank itself, and not in the pump. This simplifies the operation, and diminishes the number of tanks required in the treatment. It also furnishes an easy means of getting rid of the insoluble impurities of the cyanide (the so-called carbide of iron), which would otherwise accumulate as a black slimy deposit in the concentrated solution tank. This insoluble residue is of course discharged with the tailings when the tanks are emptied.

Another difficulty frequently encountered in the application of the cyanide process is the treatment of "battery slimes," i.e., the very finely-divided material produced during the crushing, and which has a tendency to accumulate in pasty masses. These either resist the penetrating action of the cyanide or retain the dissolved gold during the leaching operation. No satisfactory method of breaking such material has yet been devised—the evil may be lessened by mixing the slimy tailings with clean coarse sand.

Various improvements have been introduced in the mechanical details of construction. The large leaching vats of the Robinson Company are rapidly and conveniently discharged by means of a trap door placed in the centre of the tank bottom, and which may be hermetically closed by a patent screw fastening. The enormous underground vats of the Langlaagte Estate Company are discharged by means of a dredge, which appears to give perfect satisfaction.

Precipitation of the Gold.—The zinc shavings now in use are prepared by turning thin sheets of zinc on a lathe. These shavings are placed in wooden troughs, commonly known as "zinc boxes," and the solution from the leaching vats is allowed to flow slowly through them, depositing the gold as a finely-divided black slime on the surface of the zinc, while the zinc gradually dissolves in the liquid. After passing the zinc box, the "exhausted solution," which should not contain more than $\frac{1}{2}$ dwt. of gold to the ton, flows into a storage tank or "sump," whence it may be pumped back to the leaching tanks, when a fresh charge has to be treated. But the simple replacement of gold by

zinc is not the only reaction which occurs in the zinc box; it is found that a notable falling off in the strength of the cyanide occurs, due to secondary reactions caused by the gold-zinc couple.

The zinc boxes are usually divided into several compartments so arranged that the liquid flows alternately upward and downward through the shavings. The shavings are placed in a tray, the bottom of which is an iron wire screen of about four holes to the inch. This is supported a few inches from the bottom of the zinc-box. The fine "gold slimes" fall through this screen, and may thus be separated from the undecomposed zinc when the "clean up" takes place.

The zinc boxes in use at the Robinson works are about 20 ft. long, 2 ft. wide, and 2 ft. deep, with inclined bottoms. They are divided into compartments of about 20 in. in length. Each compartment holds about a bushel of shavings, weighing perhaps 40 lb. Seven compartments in each zinc box are filled with shavings, a single compartment at the head is left empty to receive any sand that may be carried through the filters by the solution from the tanks. A double compartment at the foot is also left empty to allow any gold that may be carried away by the stream of liquid to deposit before the solution flows into the sump. About 60 tons of solution, which is the quantity required for treating the ordinary daily charge of 225 tons of tailings, are allowed to run off through two zinc boxes in about nine hours. This solution may carry from one to three ounces of gold per ton of liquid; after passing through the zinc boxes it rarely contains more than 2 dwt., and should not contain more than $\frac{1}{2}$ dwt. if the precipitation has been properly carried out.

There are two sets of zinc boxes, one to receive the "strong solutions" (0.6 to 0.8 per cent. cyanide), and one for the "weak solutions" (0.2 to 0.4 per cent.). The slimes formed in the weak boxes are as a rule much poorer than those in the strong boxes, and less consumption of zinc takes place in them.

The total amount of zinc consumed amounts to about 100 lb. a day. Two men are constantly employed at the lathes, so that the turning is an arduous and somewhat costly operation. It is desirable to use freshly-turned zinc, as the surface rapidly oxidises and becomes much less active in precipitating the gold.

The most vigorous action of course takes place in the compartments which first receive the solution from the tanks. It is here that the zinc dissolves most rapidly, and is accordingly replaced by shavings from the lower compartments, while fresh zinc is continually added as the last compartment becomes empty.

The clean-up takes place once or twice a month. The screens containing the undissolved shavings are lifted from the zinc boxes. The boxes are then left undisturbed for an hour so as to allow the zinc-gold slime to settle at the bottom. The liquid is then drawn off by a syphon until very little is left above the slimes. The box is then cleaned out, and the slimes and muddy water allowed to drain through a screen of 40 meshes to the inch. The mass, consisting of water, finely-divided gold, and very fine zinc, is rubbed through this screen by means of a short stick 5 or 6 in. in length, to the end of which is fixed a piece of india-rubber.

The stuff remaining on the screen consists almost entirely of unconsumed zinc, fine enough to pass through a screen of 12 meshes to the linear inch. This is replaced in the first divisions of the zinc boxes over a fresh lot of shavings.

The slime, consisting of finely-divided gold and silver, with a large proportion of zinc and lead, and a certain quantity of tin, antimony, organic matter, and other accidental impurities, is allowed to settle in a small tank placed beneath the 40-mesh screen, and is now ready to undergo the drying and smelting operations necessary for its conversion into bullion.

In the Molloy process alluded to already, the use of zinc is dispensed with altogether. The solution passes through a shallow trough containing mercury, in which is an inner cylindrical vessel filled with solution of carbonate of soda; the edges of the cylinder just dip beneath the mercury, so that its contents are entirely cut off from the outer portion

of the vessel. A rod of lead dips into the soda solution; the lead and mercury are connected with opposite poles of the battery, and the solution is electrolysed by the passage of a current. The sodium combines with the mercury to form sodium amalgam, which at once decomposes the gold cyanide solution with formation of ordinary gold amalgam, sodium cyanide being simultaneously produced. It is claimed that much less decomposition of the cyanide takes place than with zinc, and, moreover, that the outflowing solution is better adapted for dissolving fresh quantities of gold. It is obvious that in the ordinary method a large accumulation of zinc in the solutions must take place, which in time would render them valueless for gold extraction, whereas sodium cyanide is just as effective as the potassium compound.

Production of Bullion.—The slimes are now transferred to enamelled iron pans, and carefully dried over a small furnace. This is a tedious operation, and requires considerable time. The pans in use at the Robinson works contain about 5 or 6 gallons of dried precipitate. This may contain as much as 150, or as little as 20 oz. of gold.

The precipitate, when nearly dry, is mixed with sand, borax, and bicarbonate of soda, and melted in a No. 60 crucible at a fairly high temperature. The material melts very easily, forming a very liquid slag, which, however, rapidly corrodes the pots, so that a good 60 crucible rarely lasts for more than eight meltings. The charge is not added all at once, but as each portion melts and sink down fresh quantities of the mixture are added. When the pot is full of liquid slag it may contain from 100 to 150 oz. of bullion. Large quantities of oxide of zinc are volatilised during the melting, which carry off a very appreciable amount of gold. The zinc fumes, together with the products formed by the decomposition of the cyanide salts, render the operation anything but healthy.

The bullion produced is whitish in appearance, and about 650 fine. It is very hard and brittle, and the bars are by no means uniform, so that it is difficult to obtain an accurate assay. In addition to zinc, they contain silver, lead, and sometimes a little copper.

Scope of the Process.—In its present phase the limitations of the cyanide process appear to be:—

(1.) That it is only completely successful with "free-milling ores." Pyritic ores may be treated, but at a greatly increased cost.

(2.) That it is not applicable to ores containing a considerable percentage of coarse gold.

(3.) That it cannot be economically applied to rich material.

On the other hand, the cyanide process is admirably adapted for recovering the so-called "float gold," i.e., gold

in an extremely fine state of division which remains suspended in the water for several hours, and cannot be obtained by any process of amalgamation or concentration. That the cyanide process is well adapted for the treatment of Rand ores is shown by the fact that although the system has been in use little more than two years, over 40,000 tons of tailings are now being treated per month.—W. S.

A New Method of Assay of Antimony Ores. A. Carnot. *Annales des Mines*, 1, 1892, 303; *Proc. Civil Eng.* 100, (iv.), 52.

See under XXIII., page 941.

The Action of Sulphuric and Nitric Acids on Aluminium. G. A. Le Roy. *Bull. de la Soc. Ind. de Rouen*, 1891, 232.

ACCORDING to Deville, Wurtz, Hunt, Langley, Roscoe, and others, who have written on the subject of aluminium, that metal is entirely unaffected by sulphuric and nitric acids, whether dilute or concentrated. The author having in consequence been induced to study the possibility of replacing lead and platinum by aluminium in chemical manufactories, has been surprised to find that these statements are entirely incorrect, and further experiments have therefore been made with four different samples of the metal, the composition of which is given below, in order to determine the rate of solution. Two of these, A and B, were made by Deville's process, at the former Nanterre works, by Messrs. P. Morin and Co., the others were of a more recent make:—

	A.	B.	C.	D.
Aluminium	98.28	98.45	99.60	99.47
Iron	1.60	1.30	0.30	0.40
Silicon	0.12	0.25	0.10	0.13

The samples which were cut into thin plates, and cleaned from grease by a solution of soda, were exposed to the action of acid for given periods, after which the loss of weight was determined, after washing with water and alcohol, and drying in an air-bath. From the loss of weight, the amount dissolved in the day of 12 hours, per square metre of surface exposed, has been calculated as follows:—

Solvent.	Quality.	Specific Gravity.	Temperature.		Sample Treated.			
					A.	B.	C.	D.
Sulphuric acid	Pure	1.842	° B.	° C.	Grms.	Grms.	Grms.	Grms.
			65	15 to 20	18.4	18.9	16.4	16.5
	Common	21.0	21.3	17.5	16.4
	Pure	1.711	60	..	24.5	25.0	22.0	20.0
"	Common	25.8	25.7	24.6	22.1
	Pure	1.589	55	..	19.0	18.0	17.9	16.3
	"	1.263	30	..	4.6	..	2.6	3.4
	"	1.383	40	..	17.0	16.0	15.5	14.5
Nitric acid	"	1.383	40	..	20.5	19.6	18.0	16.6
	"	1.332	35	..	16.3	16.3	14.0	13.4
	"	1.842	65	150	249.0	225.0	150.0	200
	Common	1.842	65	150	267.0*	250.0	210.0	220
Sulphuric acid	Pure	1.383	40	100	Violent action.	
	Common	1.383	40	100		

* This corresponds to a thickness of about $\frac{1}{16}$ millimetre per square metre.

From this it is evident that pure aluminium is so rapidly attacked by strong acids, even the cold, as to be quite unfit for use in apparatus for the manufacture of these acids.

—W. S.

The Effect of Heat on Mercury Compounds. F. Janda. Oester. Zeits. für Berg- und Hüttenw. 1891, 583; Proc. Inst. Civil Eng. 108, 88.

The sulphide, oxide, sub-oxide, sub-chloride, and basic sulphate of mercury are completely decomposed by heat when mixed with forge scale (magnetic oxide of iron) under a covering of zinc oxide, but the chloride shows a loss of 8 per cent., and the normal sulphate of 4 per cent. volatilised unchanged by the same treatment. When the zinc oxide cover is omitted the mercury obtained from cinnabar is almost always blackened with amorphous sulphide.

Theoretically, the mercury contained in these compounds is as follows:—

	Per Cent.
Mercuric oxide HgO	92.5
Mercurous oxide Hg_2O	96.1
Mercuric sulphide HgS	86.2
Mercuric chloride HgCl_2 (corrosive sublimate).....	73.8
Mercurous chloride Hg_2Cl_2 (calomel).....	81.9
Mercuric sulphate HgSO_4	67.5
Basic mercuric sulphate Hg_2SO_6 (Turbeth mineral).....	82.1

These figures are realised in the new Idria method of assay with iron oxide and zinc, using a gold dish for collecting the mercury, except in the case of the sulphate and chloride, which gave lower results.

When heated without any reagents, the following facts have been observed:—

Mercuric sulphide (cinnabar) is changed to metallic mercury, sulphur dioxide, and, to a small extent, to black sulphide.

Mercuric oxide darkens, and at very low red heat is changed to mercury and oxygen; the salts of this oxide volatilise with partial decomposition. Mercuric chloride volatilises almost without any change, only about 5 per cent. being reduced to metal, as does also mercuric nitrate, which is but very slightly decomposed by heat.

Mercurous oxide changes at 100° into mercury and mercuric oxide, and by further heating is completely reduced to metal with the separation of oxygen. The salts of this oxide are all decomposed at a red heat. Mercurous chloride is completely volatilised without decomposition. Mercuric sulphate, which is white when cold, turns yellow and melts to a brown fluid, which gives the original white salt when solidified and cooled. At a higher temperature it is completely volatilised without change, but more slowly than any of the other compounds.

Turbeth mineral, a basic sulphate obtained from HgSO_4 , by washing it with a large quantity of hot water, which results in the formation of free sulphuric acid and yellow turbeth ($3\text{HgSO}_4 + 2\text{H}_2\text{O} = \text{Hg}_2\text{SO}_6 + 2\text{H}_2\text{SO}_4$) is completely volatilised with decomposition when heated for about four times as long as the oxide or chloride.

The mercurial flue-stuff (*stupp* of Idria, *hollines* of Almaden), which is of the following composition:—

Metallic mercury	81.04	} 86.52 Hg
Mercuric sulphide	5.76	
Basic sulphate	0.52	
Mercurous chloride	0.12	
Mercuric chloride	} Trace	
Ammonium sulphide		
Calcium sulphate	2.71	
Magnesium	0.21	
Hydrocarbon	2.66	
Carbon (soot)	6.46	
Silica	0.15	

decomposes by heat into metal and mercury-black, a finely-divided mixture of metal and sulphide. This black powder, when mixed with and distilled under a cover of lime, gives metallic mercury, which also happens when the cover is omitted, and only 25 per cent. of lime is used in the mixture, but with a larger loss. The amalgam obtained on the gold plate is bright, with only a slight covering of hydrocarbon

oil. Mercuric chloride and sulphate are not completely decomposed by lime alone, and the deposited amalgam is covered with a sublimate of the unchanged salt.

When cinnabar, or flue-soot is mixed with 25 per cent. of lime and 25 per cent. of lamp-black, which contains both carbon and hydrocarbons, and heated for 15 minutes, the mercury is almost completely recovered, but the deposit is coated with black. The oxide and lower compounds are completely decomposed, giving a clear amalgam by the same treatment; but the higher chloride and basic sulphate show a loss of 8 and 4 per cent. respectively, or the same as in the method of assay with iron and zinc oxides.—W. S.

Smelting the Phosphoric Ore of Gellivara. Stahl und Eisen, 1892, 490; Proc. Inst. Civil Eng. 110 (iv.), 37.

At Finshtytte, in Sweden, experiments have been made in smelting the waste ore of Gellivara, which consists chiefly of apatite and magnetite with some rock, and contains from 20 to 25 per cent. of iron, being in fact a ferriferous apatite. In order to prevent the slag from taking up silica by corrosion of the bricks in the hearth and boshes, the lower part of the furnace, to a height of 6 or 8 in. above the tuyeres, was built of carbon bricks. The ore was for the most part reduced to the size of coarse sand, which rendered the working of the furnace so difficult that pieces of nut size were added to keep the charge open. Only 110 ewt. of unroasted ore were smelted in four days, with air heated to 120 or 150°C ., both alone and with various fluxes of quartz and lime. The best results were obtained without lime, or with at most 10 per cent. The slag, which ran very liquid, was crystalline when cooled, and of a grey or greenish colour, with white enclosures consisting chiefly of semi-fused pieces of apatite. The composition was:—

	A. With Ore alone.	B. With 10 Per Cent. of Lime.
Silica.....	26.20	21.45
Alumina.....	1.59	3.62
Ferrous oxide.....	1.40	0.13
Manganous oxide.....	0.20	0.28
Lime.....	43.80	18.15
Magnesia.....	5.16	5.95
Phosphoric acid.....	15.48	17.38
Titanic acid.....	2.30	2.00
Sulphur.....	0.16	0.21

The proportion of phosphoric acid is fully equal to that in the slag of the basic converter, but the state of combination is somewhat different, only 7.5 per cent. being soluble in citric acid, while in English and German basic slag the soluble part is 14.5 per cent. Both kinds are, however, much more readily decomposed by acid than apatite, and their solubility would probably be increased by using more lime.

The metal corresponding to these slags contained:—

	A.	B.
Phosphorus.....	10.61	11.86
Combined carbon.....	0.50	0.65
Silicon.....	0.08	0.09
Sulphur.....	0.03	0.02

When tapped it ran very fluid without giving off sparks, and cooled to a silvery white metal, which was very brittle, breaking with a wire-like crystalline structure, and very

similar in appearance to ferro-manganese. The composition is a very remarkable one, as, apart from the phosphorus, the analysis is essentially that of a steel.—W. S.

Progress of the Metallurgy of Nickel. D. Levat. *Annales des Mines*, **1**, 1892, 141; *Proc. Inst. Civil Eng.* **110** (iv.), 54—60.

NICKEL is found in New Caledonia in a single mineral, *Garnierite* or *Noumeite*, a hydrated silicate of nickel and magnesium, of a bright apple-green colour when pure, which is deposited in concretionary masses in the fissures of serpentine rock. The mode of occurrence indicates clearly that the mineral has been deposited by water in the form in which it is now found. The distribution of the mineral through the serpentine matrix is not arbitrary, it being always found at or near the contact of the rock with the red clays, but never in the clay itself. These masses of clay are products of the decomposition of the serpentine, and contain all its constituents and in addition, manganese, cobalt, and chromium.

The nickel ore, which is newer in origin than those of manganese and cobalt, is found as vein-matter in hollows resulting from the shrinking of the red clay from the sides of the rock funnel enclosing it. These veins vary very much in size, the maximum breadth being about 8 metres, but in some cases the whole of the rock is filled with small veins of mineral, so that it may be worked as a whole up to a thickness of 250 ft. By far the larger number of the workings are in open cast, at altitudes varying from 300 to 600 metres above the sea level, where it is easy to follow the richer developments, and with a comparatively small preliminary outlay to make provision for some years of quarry working in the same locality. The preliminary working is mainly in the direction of removing the red clay, which can only be imperfectly separated from the ore by washing, and the iron ore it contains, if left behind, impoverishes the yield of nickel, besides being objectionable in the smelting, by reason of its adding alumina to the charge, which is refractory through the presence of silica.

The mineral is carefully sorted by hand at the quarries and divided into rich and poor qualities, the former containing 8 per cent. and above of nickel, and the latter all below that limit. These are confined to simply washing away the red clay, and even this preparation cannot be carried too far without risking considerable loss (up to 3 or 4 per cent.) in the mud washed away. Hence the necessity of carefully clearing the waste away before working the mineral. The quarry waste, containing 3 to 4 per cent. of nickel, is not utilised.

The treatment of the mineral has undergone several modifications before arriving at the present practice. The old method of concentrating the metal as sulphide by the addition of pyrites or sulphur is adopted. The average composition of the ore available for smelting was: silica, 45 to 50; iron, 16 to 14; nickel, 8 to 7; magnesia, 12 to 10; alumina, 3 to 5; water and oxygen, 16 to 14 per cent.

This requires from 25 per cent. to 30 per cent. of bases (oxide of iron or limestone), besides a sulphurising material. As neither gypsum nor pyrites, free from arsenic and copper, was available for the latter purpose, the charge for the blast furnace was made up as follows:—

	Kilos.
Ore.....	1,000
Coral.....	300
Sulphur.....	35
Small coal or coke.....	75

The greater part of the sulphur passed into the regulus, and a fluid slag was obtained with 48.0 per cent. of silica, 12 to 13 of iron, and not more than 0.10 per cent. to 0.45 per cent. of nickel, but the local smelting was given up owing to difficulties in procuring coke, and now the ores are for the most part smelted in England, alkali waste being used as flux. The consumption of coke is about 20 per cent. of the weight of the charge, or about 30 per cent. of that of the ore treated. Small-sized water-jacket cupolas, smelting from 25 to 30 tons in 24 hours are used. The

product contains nickel 50 to 55, iron 25 to 30, and sulphur 16 to 18 per cent., the latter being necessary to make the regulus sufficiently brittle to be easily powdered. The subsequent concentration may be done either in the reverberatory furnace or the Bessemer converter. In the former two calcinations, followed by fusion with quartz sand, are necessary for the removal of the iron. The furnace treats 2 tons in 24 hours, with the consumption of an equal weight of coal. The operation, which lasts eight hours, is controlled by sampling during the progress, and is stopped when the iron has completely disappeared, in order to prevent loss of nickel in the slags, which, however, are not thrown away, but are returned to the ore-furnace as they fine an excellent flux, besides containing $2\frac{1}{2}$ per cent. of nickel. By the first concentration the iron is reduced to 2.5 to 3.0 per cent., and by the second to 0.5 to 0.75 per cent., the sulphur being kept to 16 per cent. at least. In the Bessemer converter the concentration is more rapidly done, a charge 1 ton of regulus melted in a cupola is introduced into the converter and blown with air at a pressure of about 40 centimetres of mercury. The temperature rises from the combustion of the sulphur, and sand is added to flux the iron. If the proportion of the latter metal does not exceed 36 per cent. it may be completely removed in about one hour and 20 minutes, but with a larger quantity the bath should be skimmed after blowing for 25 minutes and fresh flux added, as the fining will be imperfectly done if too large a quantity of slag is retained in the converter. When the slags begin to show signs of containing nickel oxide the refined metal is poured into moulds. It contains less than 0.50 per cent. of iron. Arsenic, antimony, and silver are removed either in the slags or by the blast; cobalt remains with the nickel sulphide.

The converter slags are much richer than those of the reverberatory furnace, containing from 14 to 15 per cent. of nickel, mostly as shots of diffused regulus, which may in part be collected by running the slag into conical pots and separating the cake of metal at the bottom. The whole of it must in any case be returned to the ore furnace.

Attempts have been made to continue the blowing up to the complete removal of the sulphur to produce a material that would only require a final reducing treatment to obtain pure nickel. This has, however, been found to be impossible, owing to the high affinity of nickel for sulphur, the heat developed in such an afterblow being less than sufficient to counteract the cooling effect of the air, and as the product when free from copper has a high melting-point approximating to that of iron, it sets very rapidly, and blocks up the tuyeres.

The refined regulus, whether obtained from the reverberatory furnace or the converter, consists essentially of nickel sulphide (or nickel and copper sulphides, if obtained from pyritic ore like that of Canada), with not more than 0.50 per cent. of iron, and the same proportion of other foreign matters. It is crushed to pass a 65-mesh sieve, and charged in quantities of 600 kilos. upon the bed of a reverberatory calciner 10 meters long and 2.50 metres broad, with four working doors on one side, forming a layer about 2 in. thick, which is constantly rabbled and moved gradually from the flue of the fire-bridge end. The operation lasts eight hours with pure nickel sulphide, and only six when the regulus contains copper.

The consumption of coal is 2,000 kilos. for 2,400 kilos. of material roasted. The temperature is kept to dull redness, except towards the end, when the furnace is raised to bright red heat. The finished product, which should not contain more than 1 per cent. of sulphur, is ground to pass a sieve of 120 mesh, and subjected to dead roasting in a furnace of the same breadth as the preceding one, but with a shorter bed. The charge is 500 kilos. renewed every six hours, and the temperature is kept at bright redness; 3 tons of coal are burnt in 24 hours. The product is nickel oxide or nickel and copper oxides, and should not contain more than 0.40 per cent. of sulphur.

The reduction of the oxide is effected by mixing it to a paste with flour or other organic matters, dividing into small pieces when dried, and strongly heating with charcoal powder. Formerly the paste was cut into cubes of 12 to 15 millimetres, but in France discs of regular shape, 50

millimetres in diameter and about 15 millimetres thick, made in a press, are preferred. They must not be made thicker, or the reduction will be imperfect in the centre. The Chinese, who are somewhat considerable consumers of nickel, prefer to have it moulded into ingots similar to those used as money in China.

Formerly the reduction was effected in crucibles holding 50 to 60 kilos. in a gallery or reverberatory furnace, but owing to the imperfect and irregular heating the process was very wasteful of fuel, and the pots did not last for more than five or six operations. This method has therefore been abandoned in favour of furnaces working continuously. The first of these is a large muffle 3.5 metres long and 1.8 metre broad, heated by the flame of a gas-furnace, which is passed several times round it by a series of spiral flues. The shorter sides are closed by balanced doors, and the iron pots containing the mixture of oxide and charcoal are subjected to a gradually increasing heat for 24 hours, being entered at the coolest side and pushed gradually nearer to the fireplace. This, with mixed oxides, gives a coherent product; but pure nickel oxide, although it is reduced by carbon at a comparatively low temperature, must be subjected to a temperature of 1,100° or 1,200° for four hours to obtain the coherent metallic character required by the consumer; and, as such a heat is unattainable in the muffle, the operation must be finished in a crucible furnace.

Another and more improved plan of reduction is in a regenerative furnace resembling that used for reducing zinc oxide in Belgium, but having retorts open at each end. The mixture of oxide and charcoal is charged by a semi-circular scoop at one end, and when finished the charge is pushed out at the other end into closed receivers, where it is allowed to cool out of contact with the air. A furnace with 22 retorts is capable of reducing 1,500 kilos. of nickel oxide, or 3,000 kilos. of nickel copper oxides, in 24 hours, the charge of 750 or 800 kilos. requiring 10 hours in the furnace in the first and five hours in the second case. About 2 tons of coal are required for heating in the 24 hours, and the work is done by two men per shift of 12 hours.

The reduced metal is sifted to separate the cubes or discs from irregular and broken masses, which are afterwards collected by a magnet. The former are polished by friction upon each other on a rapidly rotating barrel, while the latter is added in packing the barrels to make up the exact weight of 100 kilos.

Among the more important recent applications of nickel is that of the alloy (20 of nickel with 80 of copper) for the casing of bullets for the small-bore rifles adopted in modern armament. This combines a higher tenacity than that of the best brass with a high coefficient of elongation, the former being from 28 to 31 kilos. per square millimetre, and the latter 25 to 35 per cent., and exceptionally as much as 39 per cent., in the metal as cast. The coefficient of elongation increases with the freedom of the alloy from iron. By rolling cold, the tensile strength is increased to 60 or 62 kilos., and the elongation is diminished to 3 or 4 per cent. When annealed under the most favourable conditions the strength is 30 to 40 kilos., and the elongation 32 to 39 per cent., as compared with copper, where the corresponding figures are 25.1 kilos. and 34.1 per cent.

The annealing of this alloy is a very delicate operation, requiring special manipulation, the details of which are mostly kept secret by the manufacturers. The principal object is to avoid oxidation, and this, according to the author, may be most effectually done by separating the sheets in the annealing piles by sheets of eardboard, which are carbonised during the process. If badly annealed the mechanical properties are altered in a remarkable manner, the burnt metal having a tensile strength of 30 kilos., with only 1 per cent. elongation. In a general way the annealing is considered to be bad if the tensile strength is below 33 kilos., and the elongation less than 30 per cent. The elastic limit is from 11 to 15 kilos. when well annealed, and 45 kilos. when the metal is hard from the rolls.

The ready malleability of this alloy seems to render it particularly suitable for locomotive fire-boxes, and plates for this purpose were exhibited by the Société des Métaux at the last Paris Exhibition.

The production of nickel, which was about 400 tons in 1878, the period of the discovery of the New Caledonian ores, rose to 1,200 tons in 1880, and 2,000 tons in 1884. The application of the metal to military purposes in 1886 created an extra demand of 400 to 500 tons per annum, and in 1887 the total consumption of the world was about 3,000 tons, of which amount New Caledonia supplied about 2,600 tons. Since that date the mines of the district of Sndbury have been largely developed, and at the present time copper-nickel regulus is equal to the daily output of 12 to 15 tons of pure nickel, or from 4,500 to 5,000 tons per annum. In New Caledonia arrangements are being made for an equal production, so that in the near future a total supply of from 9,000 to 10,000 tons of pure nickel per annum is likely to be available from these two sources.

In 1876 the price of refined nickel, which was then 18 francs per kilog., fell rapidly to 10 francs and 6 francs, and ultimately, in 1886, to 5.50 francs to 5 francs, which rates have been nearly stationary ever since.—W. S.

PATENTS.

Improvements in the Treatment of Iron and Basic Slag, and in Extracting Silicon and Phosphorus. W. P. Thompson, Liverpool. From B. Talbot, Chattanooga, Tennessee, U.S.A. Eng. Pat. 10,583, June 3, 1892.

The iron is purified by pouring it while molten through a deep column of basic slag contained in a suitable vessel outside the furnace. The metalloids and other impurities combine with the slag, so liberating the heat necessary to maintain the slag in a fluid state.—J. H. C.

An Improved Process of or Means for Extracting or Recovering Metal from Ores or other Metal-Bearing Bodies. W. Noad, Upton Park, Essex; C. Minns, Westminster; and P. H. Stevens, London. Eng. Pat. 9784, June 9, 1891.

A SOLVENT is used which is prepared by mixing hydrochloric acid, about 100 galls.; saturated solution of edcium hypochlorite, about 100 galls.; sodium or potassium nitrate, about 50 lb. (but varying according to the class of ore or metal to be treated); water, about 750 galls. The clear liquor, after settlement, is the solvent required, and the finely-crushed ore is treated with it in tanks, at first without, and afterwards with agitation and heating. The metals dissolved are then recovered from the solution by successive precipitation in separate tanks.

The chemical constituents of the solvent may be compounded in a dry form for export by concentrating the hydrochloric acid to about half its bulk, completely drying the requisite proportions of the calcium hypochlorite and sodium or potassium nitrate, thoroughly mixing them with the concentrated acid, adding, if necessary, sodium chloride or other suitable dry and absorbent material, and evaporating the whole to dryness.—J. H. C.

Improvements in the Extraction of Gold and Silver from Ores or Compounds containing the Same. H. Parkes, Dulwich, and J. C. Montgomerie, Stair. Eng. Pat. 11,342, July 3, 1891.

According to this process the finely-divided ore is treated with a chlorinating or oxidising solution containing manganese dioxide and hydrochloric acid, hypochlorite of calcium, sodium, potassium or magnesium and hydrochloric acid, or chromic or chlorochromic acid and hydrochloric acid. Such solutions as these do not dissolve appreciable quantities of gold or silver, but merely render the ore more susceptible to a subsequent treatment with an alkaline potassium cyanide solution. Any gold or silver which is dissolved by the chlorinating or oxidising solution is separated by ferrous sulphate or other precipitant. Ores rich in gold may be advantageously treated with hydrogen peroxide or oxygen under pressure in presence of the chlorinating agent; rich ores of a refractory nature are

treated in a similar manner, but with the addition of potassium cyanide to the chlorinating solution. Some ores are subjected to the action of a mixture of lead and sodium chlorides saturated with chlorine or bromine. Ores which are treated with potassium cyanide or other solvent in the presence of oxygen or hydrogen peroxide may, in the same solution, be subjected to the action of sodium chloride saturated with chlorine or bromine; copper chloride or sulphate may also be added to the liquid.—W. J. P.

An Improved Method of Smelting Complex Silver Ores.
C. James, Swansea. Eng. Pat. 13,740, August 14, 1891.

THE inventor smelts silver ores rich in zinc in a reverberatory furnace in place of in the blast furnace at present employed; loss of lead and silver is thus prevented. Sulphuretted silver ores are pulverised and intimately mixed with the quantity of litharge necessary to oxidise all the sulphur present; this mixture is smelted in the reverberatory furnace, and the reduced lead is found to contain nearly all the silver. Should the ore contain zinc blende, a preliminary calcination is necessary to convert this into zinc oxide; galena is then added, and the whole smelted just as when litharge is employed. Halogenated silver ores are smelted with a mixture of galena and litharge in such proportions that metallic lead is produced; the reduced silver then alloys with the lead and is extracted by the usual methods.—W. J. P.

Improvements in the Process of Smelting Copper or Copper Ores, and in Furnaces or Apparatus applicable therefor. J. H. Bilby, St. Helens. Eng. Pat. 16,273, September 24, 1891.

THE ores and fluxes are melted in a cupola furnace and then run off into a settling furnace where the ore separates from the slag. After running off this slag, the regulus is exposed to blasts of air, preferably in a third furnace, till it contains from 70 to 80 per cent. of copper, when it is run into an ordinary reverberatory furnace to be finished into blister copper. The furnaces all communicate by channels or gutters.—J. H. C.

Improvements in and relating to the Manufacture of Wire, Sheet Metal, and the Like. C. F. Claus, London. Eng. Pat. 16,553, September 29, 1891.

IN the manufacture of iron or steel wire, the "wire-rod" as usually obtained is coated with iron oxide, and has therefore to be pickled before it can be drawn. The inventor removes the oxide by subjecting the hot wire-rod to the action of hydrogen, coal-gas, purified water-gas, or other producer-gas; the wire is then drawn in the ordinary manner. This process also obviates the necessity of frequently annealing and subsequently pickling the wire, which is so great an inconvenience in the ordinary process of drawing. Sheet metal also, if treated in the above manner, may be rolled without annealing.—W. J. P.

Improvements in Means or Apparatus for Extracting Precious Metals from their Ores. F. Webb, Walworth, Surrey. Eng. Pat. 17,636, October 15, 1891.

THE crushed ore is agitated with an appropriate solution by means of a hollow and perforated vessel or piston moving to and fro in an outer closed vessel or chamber, which is capable of being partially rotated on trunnions. These may be hollow, so as to serve as channels for the solution. Any required solution may be used, those containing chlorine, bromine, iodine, or potassium cyanide being recommended as suitable for ores containing gold.—J. H. C.

Improvements in Basic Furnace Lining and Basic Material. J. B. Alzugaray, London. Eng. Pat. 17,755, October 16, 1891.

BASIC bricks, when allowed to cool down, are acted upon by the moisture and carbonic acid of the air, and develop splits and cracks, and need frequent renewal. To obviate this objection, the patentee uses, as the chief ingredient of his basic linings, barium carbonate, which is stated to be free from these defects on account of its stability being greater than that of the carbonates of the other alkaline-earth metals, and because of its tendency to form barium dioxide. It may be used alone or mixed with magnesia, magnesium carbonate, alumina, bauxite, lime, or carbonate of lime, dolomite, strontianite, ilmenite, wolfram, scheelite "chromate," oxides and carbonates of iron and manganese, "magnetic iron," hematite, &c. The agglomeration of the mass may be effected by the use of a little silicate of soda, from 2 to 5 per cent. of the whole weight, and in certain cases 20 to 50 per cent. of plumbago may be added.—B. B.

Improvements in the Manufacture of Iron, and in Fuel or a Compound suitable therefor. W. A. Sngden, Keighley. From W. R. Sngden, Fall River, Wisconsin, U.S.A. Eng. Pat. 18,442, October 27, 1891.

See under H., page 899.

Improvements in the Manufacture of Iron. H. Le Neve-Foster, Brierley Hill, Staffordshire. Eng. Pat. 19,118, November 5, 1891.

IN preparing refined iron suitable for puddling a basic or neutral lining is employed in a regenerative or other suitable furnace. Calcined or shrunken dolomite, with or without an admixture of basic slag or chrome iron ore, is used to deprive common pig iron of phosphorus and silicon.—J. H. C.

Improvements in Leaching Ores and in Apparatus therefor. S. H. Johnson and C. C. Hutchinson, Stratford, Essex. Eng. Pat. 19,389, November 10, 1891.

A FILTER-PRESS is used having chambers which can be varied in depth according to the mechanical condition and permeability of the ore under treatment, and this is worked in conjunction with a pneumatic forcing receiver, with an agitator for the purpose of working fine ores and slimes.

The material to be filtered should be supplied at such a rate as to fill the chambers in about three minutes, and under a gradually rising pressure, finally at about 50 to 60 lb. per square inch.—J. H. C.

An Improvement in Copper Alloys. A. K. Huntington, London, and J. T. Prestige, jun., Deptford. Eng. Pat. 19,771, November 14, 1891.

THIS invention is based on the particular property of nickel which enables it to alloy in any proportion with either copper or iron. The claim is for copper alloys containing iron or ferro-manganese, increased by admixture of nickel. Zinc also is included in some instances. The proportions may be varied according to the tensile strength, ductility, or elasticity required in the alloy. For a strong ductile metal copper about 50 parts, zinc about 40 parts, and iron and nickel about 2 parts each are recommended. When the quantity of zinc is lessened that of iron, with its due proportion of nickel, is increased. Thus, if the zinc be entirely omitted, iron may be employed up to 5 parts and nickel up to 6 parts with the 50 parts copper. Ferro-manganese containing about 80 per cent. of manganese may be substituted for the iron.—J. H. C.

Improvements in Apparatus for separating Crushed Pyrites and similar Heavy Substances containing Gold or other Metal. W. Seoular, Johannesburg, South Africa. Eng. Pat. 19,782, November 14, 1891.

THE washing table is suspended at the four corners by metal straps from nprights on a suitable frame in such a manner that a to-and-fro percussive motion can be given to it by means of a triple cam in conjunction with a spring. The cam, driven on a shaft, forces back the table which, on being released, is pushed forward by the spring until the stop-piece attached strikes the frame-work, when the cam comes into play again. The jerk aided by a flow of water causes the separation of heavy from light particles, the former being discharged from an outlet at the side of the table while the latter are washed away at the end. The floor of the table is of uneven surface with a triangular depression cut diagonally across it and in which the concentrates accumulate. The depression narrows and rises towards the outlet in the side through which the heavy particles are discharged and broadens out towards the end where the outlet for the light particles is situated.—A. W.

Improvements relating to the Coating of Metals. E. Norton, Maywood, U.S.A. Eng. Pat. 21,114, December 3, 1891.

THIS patent is for an improvement in connection with the ordinary process of manufacture of tin-plate. To avoid the frothing and boiling over of the hot oil when the wet sheets are inserted the oil-bath is discarded and the sheets are passed direct from the bath of water through one or more pairs of heated rolls, the surfaces of which are continuously supplied with a covering of heated oil or other suitable material. In this way the water is evaporated and the sheets are coated with oil and raised to the necessary temperature for immersion in the molten metal bath at one and the same time.—A. W.

Improvements in the Extraction and Treatment of Metals. N. Löbdeff, St. Petersburg. Eng. Pat. 2193, February 4, 1892.

By this invention ores or metalliferous substances are melted in a furnace and a saucer-shaped cup of plumbago or other carbonaceous material placed on the molten mass. A current of furnace gases is then passed over the hearth and the ore becomes reduced by the carbonic oxide which diffuses through the saucer. This process may be also employed for removing the last traces of sulphur and similar impurities in the manufacture of steel.—W. J. P.

Improvements in the Method of Desulphurising Zinc Ores. P. Hart, Fairfield. Eng. Pat. 14,264, August 8, 1892.

THE blende or other ore is ground to a fine powder and mixed with sulphuric acid of sp. gr. 1.750, generally in the proportion of one equivalent of the monohydrated acid to each equivalent of metallic zinc present. The mixture is heated in an iron or other suitable vessel to a temperature between 300° and 400° F., when gases consisting chiefly of sulphurous acid are given off and are led into the vitriol chamber for conversion into sulphuric acid. After the mixture has been thus heated it becomes still and is then transferred to a close or blind furnace and the last of the sulphur expelled by heating to a low red heat. The zinc is left behind in a state of simple oxidation, or nearly so, and ready for smelting or any other method of extraction. The advantages are the quicker roasting with less expenditure for fuel and the obtaining the sulphurous acid in a concentrated condition suitable for economic conversion into sulphuric acid, whilst at the same time the ore passes into a condition from which the metallic zinc can be readily obtained.—A. W.

Improvements in Smelting Furnaces. H. H. Lake, London. From the Oliver Aluminium Company, New York, U.S.A. Eng. Pat. 14,406, August 9, 1892.

THE principal points claimed by the inventor are "the combination of a chamber, grate bars in the lower part of the chamber, a pot at the lower part of the chamber and having its bottom below the grate bars, provided with a discharge outlet and apertures or tuyeres for admitting gas through the top of the chamber to the pot."—F. S. K.

Improvements in Apparatus for Removing when Casting Gases and Impurities contained in the Metal or Alloy. J. L. Sebenius, Nykroppa, Sweden. Eng. Pat. 14,586, August 12, 1892.

THIS is an improvement on a previous patent for obtaining solid castings by swinging round in a horizontal plane the mould containing the molten metal, the centrifugal action forcing the gases and impurities to the surface of the metal, which surface for the time being is vertical and nearest to the centre of the circle of rotation. The apparatus, of which Figs. 1 and 2 are respectively vertical and horizontal sections, consists of a shaft A carrying a distributor *a*, which contains a circular channel, the bottom of which is built with radial ridges *h*, which are steep in one direction and sloping in the other. From the lower part of these ridges holes with mouthpieces lead out, opposite each of which a mould *c* is horizontally fixed in a suitable framework B, attached to the revolving shaft A.

The mould consists of a central compartment *b* surrounded with other compartments the shape of the castings to be made, the communication between which is made by channels in the bottom plate *g*. The whole is rapidly revolved and the metal, which is poured into *a*, is by means of the ridges *h* and the mouthpieces equally distributed

Fig. 1.

Fig. 2.

APPARATUS FOR REMOVING, WHEN CASTING, GASES AND IMPURITIES IN THE METAL OR ALLOY.

among the several moulds. It runs through the mouthpieces into the central chamber *b* of each and thence through the channels *f* into the outer compartments which are gradually filled from the bottom. The gases and impurities by the centrifugal force are driven towards the surface and the castings become clean, compact, strong, and homogeneous.—A. W.

Process for Alloying the Surfaces of Metal Wires, Ships, Plates, Sheets, and the like. E. Martin, Paris. Eng. Pat. 15,058, August 20, 1892.

THE ingot, rod, or plate of metal, for instance, copper, is cleaned and immersed in a solution of chloride of zinc or other pickle to obtain a first coating, after which it is dipped into molten zinc until the metal deposited is of the desired thickness. It is then withdrawn and heated in a muffle or other furnace with exclusion of air, when the zinc alloys with the copper and produces a brass surface. The metal is then rolled into sheets or drawn into wire. A bronze surface can be obtained by using tin instead of zinc. The coating of metal may also be deposited electrolytically.—A. W.

Improvements in the Wet Process for the Extraction of Gold or Silver, or both, from Pulverised Ores or other finely-divided Material, and in Apparatus therefor. J. W. Sutton, Brisbane, Queensland. Eng. Pat. 15,248, August 24, 1892.

THE ore is chlorinated in a vertical cylindrical chlorinator in which is a screw conveyor running in a smaller cylindrical casing. The screw, on revolving at a moderate speed, carries the ore upwards inside the casing, over the upper end of which it falls into and through the annular space between the casing and the wall of the chlorinator. Thus the thorough and constant circulation of the pulverised ore with the chlorine is effected. The mixture is withdrawn into a closed reservoir, the excess chlorine removed, and the liquid separated and the ore washed with the aid of a hydro-extractor of approved form. The gold is precipitated preferably with sulphate of iron, and separated by a small hydro-extractor, the liquor being afterwards evaporated to catch any gold that might have escaped filtration.

Silver can be extracted with the same apparatus, the chlorinated ore being leached with hyposulphite after separating from the chloride of gold. If no gold is present the ore is roasted with salt and the silver separated with hyposulphite in the hydro-extractor.—A. W.

Improvements connected with the Extraction of Metals from their Ores. J. W. Chenhall, Totnes. Eng. Pat. 15,584, August 30, 1892.

A SULPHATE which will decompose on roasting is added, in quantity from 1 to 10 per cent., in addition to common salt to the ore before grinding and roasting. The sulphate of iron or copper is preferred in cases where copper or silver is present in the ore. It is stated that the calcination or roasting is thereby quickened and that the metal contents become more soluble.—A. W.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

The Colours and Absorption Spectra of Thin Metallic Films and of Incandescent Vapours of the Metals; with some Observations on Electrical Volatility. W. L. Dudley. American Chem. J. 1892, **14**, 185—190.

IN the cases of potassium, sodium and lithium, volatilisation by boiling was resorted to. The potassium vapour condensed in a film on the cooler portions of the tube, and exhibited in the thinnest parts colours by transmitted light, ranging from violet to blue, as the thickness increased, while by reflected light the film had the usual silvery

metallic lustre of potassium. The brilliant colours completely disappear, and the film assumes a frosted appearance owing to its breaking up into a number of minute globules. Sodium gave a yellow brown film, lithium a red-brown film, and in each case the glass was attacked, and the film was permanent. The colour was a source of surprise since it approached more or less closely to that of its incandescent vapour. Perhaps it may be accounted for in the same way as in gold "ruby glass," i.e., to the presence of finely-divided metal distributed through the glass.

(2.) The application of electro-deposition is limited, gold films, however, may be readily procured since it is easy to separate the film from the metal on which it is deposited, and the difficulties of the process may be largely obviated by following the method of Kundt (Ann. der Phys. Wied. **34**, 469).

(3.) The reduction of a thin film of the metallic salt was unsatisfactory, although films of platinum giving a purple colour by transmitted light could be easily obtained.

(4.) The electric arc between terminals of the metal to be volatilised was successful in a few cases, but was usually granular, and altogether unsatisfactory.

(5.) The condensed spark (Wright, Am. J. Sci. (3), **13**, 49; **14**, 169; (Hartley, Proc. Roy. Soc. **46**, 88; (Crookes, Chem. News, **63**, 287) between the two points of metal enclosed in an exhausted glass tube serves well in many cases. No relationship has yet been discovered between the degree of electrical volatility and any known constant, but a relationship might be discovered if the volatilisation were carried on under such conditions of temperature and pressure as would insure molecular conditions in each case.

If the order of the electrical volatility of the metals as found by Crookes be compared with Lothar Meyer's curve of atomic volumes, it will be found that the volatile metals lie at, or near the minima of the curves, close together on the ascending sides in the periods IV., V., and VII., alternating one from the other. Magnesium and aluminium, which are practically non-volatile, lie on the descending side of period III. Aluminium, which is less difficult to volatilise than magnesium, is nearer the minimum of the curve. The metals given in the order of their electrical volatility alternate in the periods as follows:—

Metal.	Comparative Electrical Volatility.—Crookes.	Period.
Pd.....	108.00	V.
Au.....	100.00	VII.
Ag.....	82.68	V.
Pb.....	75.04	VII.
Sn.....	56.94	V.
Pt.....	44.00	VII.
Cu.....	40.24	IV.
Cd.....	31.99	V.
Ni.....	10.99	IV.
Ir.....	10.49	VII.
Fe.....	5.50	IV.

A table is given for a number of metals, in which is given the colour of the films by transmitted light, and the colour of the incandescent vapour as observed, and as indicated from the spectral lines. The colour of a film varies somewhat with the thickness, but each metal has a strong tendency towards a characteristic colour, which is produced when the film is as thick as it can be to transmit light.

Absorption Spectra of Metallic Films.—If the same molecular conditions existed in the film as in the incandescent vapour, we would expect the same absorption; in every case examined, however, the films gave simply general absorption, no bands or lines being indicated.

Metal.	Colour of Film.	Observer.	Colour of Incand. Vapour.	Observer.	Colour of Incand. Vapour as indicated by Spectrum.
Gold.....	Pinkish, violet, blue, blue-green	Faraday, Wright, and others.
Heated to 316°....	Green	Crookes and others	Green	Dudley	Green
" on glass....	Red	Faraday and Wright
Silver.....	Deep blue	Wright	Blue Yellow-green in electric arc.	Stas Dudley	Yellow-green
Copper.....	Green	Wright, Fleming	Green	Dudley	Green
Aluminium.....	Fine blue Brownish	Fleming Wright	Green-blue	Dudley	Green-blue
Bismuth.....	Grey-blue	Wright	Blue, slightly greenish	Dudley	Blue-green
Platinum.....	Blue-grey Purple	Wright Dudley	Blue (?)	Dudley	Blue
Palladium.....	Smoky brown	Wright	Green	Deville and Debray (?)	Green
Lead.....	Smoky brown inclining towards olive.	Wright	Blue	Dudley	Blue
Zinc.....	Grey-blue, less deep than Ag, deeper than Bi.	Wright	Green-blue	Dudley	Green-blue
Calcium.....	Grey-blue about same as Zn, slightly less intense.	Wright	Green	Dudley	Green
Magnesium.....	Grey-blue, similar to Zn and Cd, but less clear.	Wright	Green	Wright	Green

Lithium " "	Dark brown-red	Dudley	Red	Arfvedson (?)	Red

—G. H. R.

The Thoferrn Electrolytic Copper Refining Process.
L'Industrie Electr. April 10, 1892; Iron, May 6 and 13,
404—405, 426.

THE process resembles the method adopted at Hamburg and Biache, but improvements have been introduced rendering the method more efficient and economical. Amongst these are—(1) the arrangement of the tanks; (2) the arrangement of the conductors; (3), the composition, heating, and circulation of the electrolyte; (4) the manufacture of anodes and cathodes; and (5) the oxidation of the anodes and the electrolyte. A description and the measurements of the tanks are given.

The dynamos are installed for a normal production of 1 grm. per ampère per hour per tank. In factories where several tons of copper are treated per day Thoferrn arranges his bath in such a way that the loss of E.M.F. per tank is not more than 1.4 volt, so that for 620 tanks an E.M.F. of 19 volts at the dynamo terminals would be required if the conductors absorb about 5 per cent. In small workshops the electrodes have a much smaller surface, and the loss of E.M.F. is about 0.3 volt.

The conductors are calculated so as to absorb not more than 5 per cent. of the total energy, or, in cases where the refining is carried on at a great distance from the dynamos, 8 per cent. The current should not exceed 1 ampère per square mm. of sectional area of the cable from the dynamo to the first row of tanks. The bars placed on the borders of the tanks need be only half the cross section, as two bars form one conductor. The bars are arranged on four rows of wooden girders placed laterally on the right and left of the tanks, the two external girders being at a slightly higher level than the two others, so that the transverse bars carrying the anodes rest only on two bars, as well as those carrying the cathodes. The bars carrying the current to

the anodes in one bath transmit it to the cathodes in the next. For this purpose each bar is twice the length of the bath, and bent in the middle to pass from one set of girders to the other. The groups of tanks are coupled by bars of special form, the baths being thus connected in series without soldering the conductors. The transverse bars supporting the electrodes are of iron, covered at the top with thin copper ribbon, and having a section of 4 centimetres by 3 centimetres. The ribbon is bent beneath the supports at each end of the bar to get contacts of copper upon copper.

The liquid is caused to circulate by means of injectors, pumps, or other apparatus continually raising it from a lower to a higher reservoir, whence it flows to the first tank, then from each tank in succession it is taken at a certain distance from the bottom by siphons to the next tank, successive differences of level of 2 centimetres between the 10 tanks of one group sufficing to ensure good circulation. From the last tank of each group the liquid flows to the collecting reservoir.

Thoferrn has devised the following mode of continuous automatic purification from the impurities with which the liquid becomes charged during working. He employs in each particular case a special arrangement for oxidising the impurities by sending a jet of air through the liquid at a temperature of, or above, 35° C. If pumps are employed to circulate the liquid, a ventilator is used to oxidise the liquid at the moment of falling into the distributing reservoir. If an apparatus similar to the one used in sugar refining is employed, the air escape of the apparatus is connected with the discharge pipe of the distributing reservoir. The action is so energetic that red spots of ferric oxide can be seen in the seum, and the reservoir should be large so as to allow the impurities to settle and the seum to disperse before passing the liquid into circulation.

The liquid is maintained at a temperature of 35° C. throughout the system with little or no extra expense by utilising the heat of coal cinders or waste steam. The anodes are made of different qualities of copper and are sometimes oxidised. In using them each one has two small lugs formed in casting, which are pierced, and by which the anode is hung so that the lug is kept above the surface of the liquid, thus preventing it from being corroded and the anode from falling to the bottom of the bath. The expenditure for attendance and for replacing the hooks is thus greatly diminished. If the plates were made large enough and suspended by strong lugs from the main conductors, all cross-pieces and hooks might be dispensed with, but large electrodes occupying almost the entire width of the bath impede the circulation of the liquid and cause the deposition on the cathode of the impurities of the anode.

To free the electrolyte from impurities a large quantity of free oxygen must be provided in the bath, and through the action of the current this accumulates near the anode, oxidising or peroxidising the impurities, thus rendering them practically insoluble. The oxidised substances form on the anode a small layer of adhesive mud which slowly flows down the walls and falls to the bottom without mixing with the liquid. This mud, being then in the neutral zone between the lower border of the anode and the bottom of the tank, and not affected by the circulation, is not subject to any chemical or mechanical influence. If the circulation of the liquid be not sufficient, part only of the impurities is rendered insoluble directly, and the remainder derives the required oxygen from the liquid itself. This action takes place throughout the entire space between the electrodes; whilst the mud produced is deposited everywhere, on the cathode as well as on the anode and the bottom of the tank, thus rendering the copper deposit very impure. The impurities, in the form of salts which accumulate in the tanks, impede electrolytic action and subsequently necessitate complete purification of the liquid.

The author has used currents of 30, 50, and even 60 amperes per square metre, but it is believed it would generally be well in refining copper not to exceed 50 amperes per sq. m. of cathode, and to use that strength of current only when all the precautions indicated by him are rigorously observed.

The composition of the electrolytic solution varies according to the quality of the copper treated and the current employed, e.g., for raw copper (92–98 per cent. Cu) and current of 30 amperes per sq. m., the composition is,—copper sulphate, 150 parts; sulphuric acid, 50 parts; and water, 800 parts. For raw copper with oxidised anodes and 50 amperes per sq. m., 200, 55, and 745 parts respectively. Finally, for copper coming from the converter containing 98–99 per cent., and afterwards properly oxidised, a current of 60 amperes per sq. m. may be used with advantage, the liquid then having the following composition:—Copper sulphate, 250 parts; sulphuric acid, 60 parts; water, 690 parts.

The cupric sulphate is generally manufactured at the works at the commencement of the electrolytic process, the tanks being filled with a mixture of 110 parts of sulphuric acid and 890 parts of water. If a current of 590 amperes would normally be used, a current of 100 amperes is passed until the composition of the liquid is that mentioned above. It will be understood that only one-fifth the normal amount of copper is deposited by this current, while the oxidised copper, dissolving easily in the acid, rapidly enriches the bath with sulphate, which is of excellent quality and is produced at moderate expense.—A. W.

Practical Notes on the Electrolytic Refining of Copper. F. B. Badt. The Electrical Engineer, New York, **13**, 1892, 598; Proc. Inst. Civil Eng. **110** (iv.), 78–79.

This paper contains a tabulated list of the various refineries electrolytically worked in the United States, the sum total of the output reaching 3,650 tons, and the capital invested in the several undertakings being over 200,000l.

The most general arrangement of vats is the ordinary multiple system of connection of plates as in secondary

cells, the anodes and cathodes being all in parallel in each vat, and the vats being connected in series and parallel to meet the electrical requirements.

The crude material is in general black copper cast into plates of convenient size, and containing 97 per cent. to 98 per cent. of pure copper, and in most of the works is the raw material introduced, though in some the plates are smelted and run from matte of 45 per cent. to 54 per cent. copper.

The solution employed is sulphate of copper, and this is in all cases purchased and not manufactured on the spot.

It should be noted that matte containing less than 30 oz. of silver per ton sells at the market price of copper matte; but if the silver is over that amount, then it is also paid for according to the assay results.

One pound of copper per hour is deposited by about 386 amperes; but the efficiency of the plant can be theoretically raised to any figure by increasing the number of vats and the size of plates, though in practice certain limits are reached which cannot be economically surpassed.

The usual density of current adopted is about 10 amperes per square foot, and this cannot be exceeded without affecting the purity of the copper deposited.

Good circulation of the liquid is also indispensable, and different methods for obtaining it are described; the most successful being afforded by two collecting tanks, into either of which the liquid flows after circulating through the depositing vats, fed from a storage-tank at higher level; these collecting tanks are used alternately, and when one is full it can be closed, and the liquid forced up to the storage-tank by air-pressure.

The scheme advocated for the dynamos is that of separate excitation of the field magnets so as to avoid reversal of current and fluctuation of the voltage.

The cost of a plant to deal with 1,000,000 lb. of refined copper per month, and driven by water-power, is put at about 25,000l., to which must be added the cost of copper under treatment, say 16,000l., and if steam power be required, an additional cost of 4,000l. must be allowed. Electrolytic refining is, therefore, expensive as regards the cost of plant, and should, therefore, be erected on carefully prepared plans of both electrical and mechanical details.—W. S.

PATENTS.

Improvements in the Extraction of Precious Metals from their Ores. W. H. Martin and W. Pethybridge, London. Eng. Pat. 14,823, September 2, 1891.

The pulverised ore, placed in a cylindrical vessel of wood or iron containing a number of iron balls, is mixed with water and ammonium formate, hydrocyanic acid, ammonium cyanide, ammonia or mercuric cyanide; a small quantity of mercury is sometimes added. The cylinder is then rotated at 100–500 revolutions per minute and an alternating or continuous electrical current of high potential passed through the material; air or steam, under pressure, is also forced into the cylinder. After 4–6 hours the solution is separated from the ore by a pump of special construction, the precious metals electrolysed on to carbon plates and the amalgam distilled.—W. J. P.

Improvements in Secondary or Storage Batteries. H. H. Lake, London. From P. Kennelly and C. J. Diss, Brooklyn, U.S.A. Eng. Pat. 16,934, October 6, 1891.

The electrodes are formed of slotted lead plates into the openings of which are inserted the frames which hold the active material which is preferably red lead. These frames are constructed preferably of a material composed of one part by weight of shellac incorporated with five parts, by weight, of finely pulverised glass (see following patent), and are provided with transverse openings expanding inwardly, and are placed one on either side of a conducting strip, and connected to it by heating them until they

become adhesive. The active material is filled into the openings in the frames which are placed in position in the slots in the plate and connected to it.—G. H. R.

Improvements in Secondary or Storage Batteries. H. H. Lake, London. From P. Kennedy and C. J. Diss, Brooklyn, U.S.A. Eng. Pat. 16,938, October 6, 1891.

This invention relates to storage batteries in which the electrical conductivity is provided by a conductor distinct from the structures which supports the active material, the latter being composed of materials which are practically non-conductors (see preceding patent). Some suitable bituminous, resinous, gummy or gum-resinous material which is capable of being brought to a plastic condition, and when in that condition of being mixed with some powdered mineral substance and moulded and subsequently setting into a solid mass which is a non-conductor. The best results are obtained with shellac and powdered glass in the proportions of one part by weight of the former to five parts of the latter.—G. H. R.

An Improved Compound for Insulating, Covering, Moulding, and Analogous Purposes. W. J. B. Banks, London. Eng. Pat. 17,831, October 17, 1891.

APPROXIMATELY equal parts of powdered slate, soap stone, or French chalk, are mixed into a stiff paste with a solution of potassium or sodium silicate, and moulded with light pressure. The articles thus formed are slowly dried and immersed in a saturated solution of calcium chloride, after which they are again slowly dried. A bath of an alkaline stearate, and then one of "compound sulphate of aluminium and potassium" may be substituted. The treated articles may be immersed in tar, bitumen, or paraffin, and may be glazed or polished by known methods.—B. B.

A New or Improved Portable Galvanic Battery. P. Stiens, Berlin, Prussia. Eng. Pat. 4185, March 3, 1892.

ACCORDING to this invention the battery is supplied with a reservoir placed on a shelf above it. This vessel is provided with three openings, one of which is in connection with the air, another is connected with the distributing apparatus, and the third with the pipe and pump which returns electrolyte from the vessel in which it collects after passing through the cells. The cells are arranged in tiers one over the other, and are hermetically sealed. The overflow from each tier is led to a counterbalanced vessel which tips up and discharges into the next lower tier of cells, the overflow from which fills the same counterbalanced vessel, and so on. The overflow from the last tier of cells passes into the lower reservoir from which it can be pumped up again into the upper. Means are provided for regulating the flow of the electrolyte.—G. H. R.

Improvements in and Relating to Electrical Accumulators or Secondary Batteries. D. Young, London. From A. E. Colgate, New York, U.S.A. Eng. Pat. 13,562, July 26, 1892.

THE plates are made of thin strips or ribbons of metallic lead which are perforated transversely in numerous rows. The strips are then corrugated and twisted loosely like a strand of yarn, and these strands are woven by any of the ordinary methods into a band or series of plates. When a sufficient number of the mats have been produced, two or three, or more of them, are laid upon one another and subjected to moderate pressure, whereby compound plates are formed sufficiently compacted to hold together in ordinary handling. The plates are then shaped by trimming their edges and fusing them by a blowpipe flame, and are then fitted into a cast lead frame by fusion of the parts in contact. The plates are then in a finished state and ready for the usual treatment or forming process.—G. H. R.

Electrodes for Secondary Batteries. J. C. Fell, London. From W. Morrison, Des Moines, Iowa, U.S.A. Eng. Pat. 14,044, August 3, 1892.

THESE electrodes are made up of elongated coils of lead ribbon which are compressed and set side by side transversely in a frame. These coils have a hollow space extending nearly their whole length, thus providing for the free circulation of the electrolyte.—G. H. R.

Improvements in Dry Galvanic Batteries. C. C. Lesenberg, Rostock, and J. von der Poppenburg, Berlin, Germany. Eng. Pat. 14,089, August 4, 1892.

THE battery consists of a zinc vessel or cup filled with finely-chopped or ground fibrous materials, such as straw, chaff, and other vegetable matters which have been steeped in hot water. Hydrates of carbon, such as dextrin, glucose, or starch may be mixed with this, and water is added so that the entire mass is moist, and yet will not give off any water. In the centre of the zinc cup is placed a cylindrical hollow carbon electrode which tapers at its upper end. This cylinder has been steeped in an aqueous solution of hydroxide of chromium which has been made by dissolving the precipitate formed on the addition of sulphuric acid to bichromate of potash solution. A small quantity of the hydroxide of chromium is inserted into the carbon cylinder, and the bottom is closed by a cork. When all the parts have been inserted the cell is sealed up.—G. H. R.

Improvements in Electric Battery Plates. E. P. Usher, Grafton, Massachusetts, U.S.A. Eng. Pat. 14,816, August 16, 1892.

THE improvements relate to battery plates which have no internal supporting frame. Tablets of finely-perforated lead filled with dry powdered oxide of lead, and having central longitudinal conducting strips protruding from one end, are taken, and these conducting strips are connected together by a transverse strip. The series of united tablets are held substantially parallel by transverse perforated strips which surround the several tablets, and project therefrom to ensure an open space between adjacent plates and tablets for the free circulation of the electrolyte.—G. H. R.

Improvements in Storage Batteries. E. P. Usher, Grafton, Massachusetts, U.S.A. Eng. Pat. 14,814, August 16, 1892.

THE bottom and sides of the battery elements are enclosed by a flexible wrapper of vulcanized rubber or similar compound, upon the surface of which inclined yielding lips are formed with a grooved space between the adjacent lips to receive the edge of the lead paste, or frame, and to hold it vertical. The lips of each pair separate at the line of meeting of their inclined surfaces to receive the edges of a separator sheet interposed between successive positive and negative plates. The battery plates are cast as a thin sheet with a series of vertical ribs or flanges projecting on opposite sides, between which ribs the active material is introduced, intermediate wells or spaces being preferably left open for more free circulation. The active material is in the form of tablets which may be introduced endwise after the plates and separators are in place. These tablets are preferably made by wrapping the proper amount of dry active material in an envelope of thin lead foil, and then flattening and perforating the envelope.—G. H. R.

Improvements in Diaphragms for Electrolytic Decomposing Apparatus. A. Breuer, Duisburg, Germany. Eng. Pat. 19,775, November 14, 1892.

THE object of this invention is to substitute for the porous partitions of clay, which soon lose their efficiency, particularly when used in the electrolysis of alkaline chlorides, a diaphragm formed of a porous cement substance which

shall be unacted on. Four methods of manufacture are given:—

First.—Sifted pieces of pumice stone or coke of from 4 to 8 mm. thick are carefully mixed with natural or artificial cement, such as lime or magnesia cement, in equal proportions, diluted with water to form a thick paste, and put in moulds. After setting, the moulded pieces can be used. The thickness of the pieces of pumice stone or coke depends on the thickness of the moulded pieces to be obtained. The pieces of pumice stone or coke mentioned in this example are suitable for the manufacture of plates of from 12 to 15 mm. thick.

Second.—35 litres of reduced rock-salt are mixed with 65 litres of natural or artificial cement, such as lime or magnesia cement, diluted with water to form a thick paste, and put in moulds. In lieu of rock-salt use may be made of other soluble salts. After setting, the moulded pieces or plates are lixiviated with water.

Third.—50 litres of natural or artificial cement, such as lime or magnesia cement, are intimately mixed with 36 litres of a solution of rock-salt, which contains about 250 grms. of rock-salt per litre, and 14 litres of hydrochloric acid, proceeding as stated in the second example. The solution of rock-salt can be replaced by other solutions of metallic salt, and the hydrochloric acid by other (inorganic or organic) acids.

Fourth.—100 litres of natural or artificial cement, such as lime or magnesia cement, are intimately mixed with 2 kilos. of cow hair or woollen yarn cut to pieces, diluted to form a thick paste and put in moulds. Such moulded pieces or plates possess after they are set such a porosity that in the use of the same a greater resistance to the current does not occur; in use the hair or the woollen fibres are gradually dissolved in the liquor, thereby rendering the plates still more porous.—G. H. R.

PATENTS.

Improved Composition for Treatment of Fibrous Material, either during or after Manufacture, also Applicable as a Household Article for Washing, Cleaning, and other Purposes. G. E. Armstrong, New York, U.S.A. Eng. Pat. 17,325, October 12, 1891.

VEGETABLE oil or grease is saponified with caustic soda of 1·16 sp. gr. From this saponaceous mass the glycerin may or may not be removed. The material is, when cold, cut into slices, thoroughly air-dried, and pulverised. It is then mixed with sodium carbonate and rosin in the following proportions:—sodium carbonate, 41·5 to 65; saponaceous mass, 10 to 33·5; rosin, 25. A solution of the above may be used for washing for household purposes, as a substitute for soda-ash in bleaching, and for imparting certain desirable properties to raw fibre.—A. J. K.

Improvements in Bleaching, Deodorising, and Purifying Fats and Oils, and Apparatus therefor. W. Mills, Peckham, London. Eng. Pat. 18,224, October 23, 1891.

THE inventor purifies and bleaches non-drying fats and oils by means of a mixture of hot air and volatilised sulphuric trioxide (anhydride) which is passed by suitable pumps and in a suitable state of sub-division (by means of perforated pipes) into a "mixer" capable of withstanding a pressure of two atmospheres. The bleaching is said to be specially efficient owing to the decomposition of the sulphuric trioxide into sulphurous acid and oxygen, both of which are acting as *in statu nascendi*. The bleached oils are finally purified by well-known methods. Three sheets of drawings illustrate the apparatus for carrying out this invention.—J. L.

An Improved Fluid Soap. F. G. Haigh and W. C. Haigh, Manchester. Eng. Pat. 18,632, October 29, 1891.

THE patent is claimed for a soap consisting of 20 parts of water, 2 parts of paraffin, 2 parts of resin, 4 parts of fat, and 1 part of caustic potash.—J. L.

Improvements in the Manufacture of Soap. J. Taylor, Leith. Eng. Pat. 19,297, November 7, 1891.

THE inventor combines a mixture of resin soap and sodium sulphate with any ordinary soap, and adds finally borax or sodium silicate.—J. L.

An Improved Cleansing Material. H. E. Walter, Brixton. Eng. Pat. 20,445, November 24, 1891.

THE improved cleansing material consists of ordinary soap with which animal or vegetable fibres are incorporated.—J. L.

A Process of Extracting, Purifying, and Saving the Fat or Grease from Wool, and for Cleaning the Wool by the use of Benzole (Benzene) or any other Spirituous Liquid suitable for Dissolving the Fat or Grease. J. Trent and G. Henderson, Christchurch, New Zealand. Eng. Pat. 15,012, November 26, 1891.

RAW wool is soaked in benzene, &c. and the dissolved fat removed by means of a press or rollers. The solvent used is recovered by distilling off the volatile benzene, &c. from the grease.—J. L.

Improvements in the Manufacture of Soap. E. J. T. Digby, London. Eng. Pat. 20,590, November 26, 1891.

A SOAP of "great hygienic and cleansing properties and much cheaper than ordinary soap" is prepared by mixing with soap, weight for weight, oyster or other shells which have been cleansed by acetic acid, powdered and "boiled with sulphate of potash, or soda, or other equivalent substance into a true paste."—J. L.

Improvements in the Separation of Wool-Wax from Wool-Fat, and in the Preparation of Lanoline from the more Fluid Residue. B. Jaffé and L. Darmstaedter, Charlottenburg, Germany. Eng. Pat. 14,114, August 4, 1892.

THE object of this invention is to separate the constituents of the wool-fat into different groups of varying hardness, the harder wax-like parts being recommended as a substitute for bees-wax, the softer being worked into lanolin by known methods. For this purpose the wool-fat is dissolved in a heavier benzene (paraffin hydrocarbon), benzene, toluene, xylene, ether, chloroform, bisulphide of carbon, or turpentine oil, and to this solution is added methyl- or ethyl-alcohol, which precipitates the harder substances of the wool-fat. The hardness and quantity of

the separated wax-like substances may be varied by the quantity of alcohol added; the smaller the quantity separated, the harder is the product, the harder substances being the first to separate. The softer fats remain dissolved and are recovered by distilling off the solvents. The same result can be obtained in a cheaper way by dissolving the wool-fat in fusel oil, acetone, acetic ether or its homologues, and cooling the solutions a few degrees below the melting point of the hardest substances. Instead of cooling the solutions alcohol may also be used for fractionally precipitating the harder constituents, as described above.—J. L.

Improvements relating to the Desulphuration of Oils. H. H. Lake, London. From O. P. Amend and J. H. Maey, New York, U.S.A. Eng. Pat. 14,405, August 9, 1892.

The patentees recommend the refinement of petroleum oils containing sulphur compounds, as Ohio and Canadian oils, by vaporising the oil, subjecting the oil-vapour, together with the sulphur contained therein, to a temperature above the boiling-point of the latter, and by this means vaporising the sulphur, then exposing the latter to the action of such chemical agents as will act upon or will combine with sulphur, and finally condensing the oil. The patentees prefer, in order to insure the complete vaporisation of the sulphur, a red heat clearly distinguishable in daylight, and have found temperatures between 700 and 1,200° very successful in practice. They recommend the use of a number of chemical substances that will unite with sulphur when vaporised, as for instance, various metals, their oxides, and sub-oxides. The oxides and hydroxides of the alkalis also give good results, but preference is given to the employment of oxidising agents, such as manganese dioxide and other higher oxides of manganese, barium peroxide, the manganates and permanganates, chromates and dichromates, chromic iron ore, and lead dioxide.—D. B.

XIII.—PAINTS, PIGMENTS, VARNISHES, RESINS, INDIA-RUBBER, Etc.

Investigation of the Properties of India-Rubber and Data for the Establishment of Rules for its Reception in the (Russian) Navy. Lieut. L. Vladimiroff, Morskoi Sbornik, St. Petersburg, 1892, 57; Proc. Inst. Civil Eng. 109, 75—76.

Owing to the want of an established system of testing vulcanised india-rubber, and to the fact that chemical analysis gives no reliable results, the author was induced to make in the St. Petersburg Technical Institute a series of experiments upon the best means of testing this substance. The samples were supplied by the Russo-American factory of St. Petersburg and by the Moscow factory of that city. The experiments were comprised under the following heads:—

- (1) The behaviour of various qualities of rubber at high temperature until the appearance of signs of damage.
- (2) The determination of the extension at the moment of rupture of test-pieces of various sectional area.
- (3) The determination of the percentage of ash.
- (4) The determination of the percentage soluble in carbon bisulphide.
- (5) The determination of the hygroscopic capacity.

The influence of temperature was determined by exposing samples, several cm. long and from 3 to 6 cm. thick, in an air-bath, to a temperature of 125° C. The samples were then bent first to an angle of 45°, and then to 180°, and were examined for cracks. It was shown that the best qualities should withstand an exposure to 125° C. for five hours without any external change.

In the second series of experiments it was proved that the extension did not sensibly vary, for a given quality, with the thickness or sectional area, and that the extension did not in any case exceed 12 per cent. of the original length of the test-pieces.

The amount of ash was found to be independent of the specific gravity and extensibility. The colour of the ash indicated the presence of certain metallic acids.

It was found that the extensibility multiplied by three times the specific gravity gave a constant = 11.1.

The solubility in bisulphide of carbon was determined in Saucote's apparatus, but did not give any practical results.

After drying in a desiccator for three weeks, no samples gave a loss in weight of exceeding $\frac{2}{3}$ per cent.

The author deduces the following conclusions from his experiments:—

(1) India-rubber should not give the slightest signs of superficial cracks on being bent to an angle of 180° after five hours' exposure in a closed air-bath to a temperature of 125° C. The test-pieces should be about 6 centimetres thick.

(2) Rubber containing not more than 50 per cent. by weight of metallic oxides, should stretch to five times its length without breaking.

(3) Pure caoutchouc, free from all foreign matter except the sulphur necessary for its vulcanisation, should stretch seven times its length without breaking.

(4) The extension measured immediately after rupture should not exceed 12 per cent. the original length of the test-piece. The test-pieces should be from 3 to 12 mm. wide, and not more than 6 mm. thick, and 3 cm. long.

(5) The percentage of ash gives a certain indication of the degree of softness, and may form a basis for the choice between different qualities for certain purposes.

Moreover, any excess of sulphur over that required for vulcanisation should be removed at the works, and should not appear on the surface of any object. Also the sulphur should not harden under the influence of frost.—W. S.

The Durability of India-Rubber Hot-Water Pipes. E. Belleruche. Rev. Univ. des Mines, 18, 1892, 25; Proc. Inst. Civil Eng. 110 (iv.), 21.

On the Grand Central Railway of Belgium the warming of the carriages by hot water circulating through pipes connected by india-rubber coupling tubes from carriage to carriage, was introduced in 1882, and from that date observations have been made in order to determine the average duration of the connecting pipes. On the Charleroi and Vireux section of the line, where the first experiments were made, the number of pipes in use increased from 26 in 1883 to 89 in 1891, the ages of which at the end of each year are given in a table, from which it appears that no loss was experienced on the original number of 26 for four years, after which they became worn out in increasing numbers, and were entirely gone at the end of the ninth year. The mean age of the tubes at work at the end of 1891 was 3.5 years. The author hopes the age will be increased by the adoption of a new system of connections which will materially diminish the wear and tear incidental to coupling and uncoupling the carriages.—W. S.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

Analysis of Commercial Yolk of Egg. F. Jean. Monit. Scient. 6, Aug. 1892, 561.

See under XXIII., page 941.

PATENTS.

Improvements in or Relating to the Finishing of Leather. B. J. Gibney, Nottingham. Eng. Pat. 18,951, November 3, 1891.

WITH the object of strengthening fragile skins or the thin portion of split skins, a sheet of linen, canvas, paper, or other material is cemented or pasted thereon. Thus prepared the skins may be put through the ordinary finishing operations which otherwise would be too severe.—W. M. G.

A New or Improved Process for the Production of Boron Sulphate Compounds, and the Application of such Products to the Unhairing of Hides or Skins, and to the Prevention of Putrefaction. E. Edwards, London. From H. Bauer and J. Gyiketta, Stuttgart, Germany. Eng. Pat. 19,637, November 12, 1891.

THE new compounds called "borol" are made by adding by degrees an equivalent part of boric acid to an equivalent part of a fused bisulphate—such as bisulphate of potash or soda—and heating the mixture to 500° C. Or under the same conditions heating a borate with a monosulphate and sulphuric acid. Water is expelled, and the new compound "borol" remains as a clear fluid mass, which, on cooling, forms a transparent, glassy, brittle body.

Thus—

The substance is soluble in water, and has an acid reaction and taste. Although containing proportionately a small quantity of boron it has greater antiseptic properties than boric acid. For these reasons it is well suited for unhairing hides and skins, and for preserving animal and vegetable substances from putrefaction.

For unhairing hides, "the pit of the tannery is to be three-quarters filled up with lake-warm water. To this water is added and mixed therewith a proportionate quantity of 'borol,' amounting to from $\frac{1}{4}$ to $\frac{1}{2}$ per cent. of the water." "The hides to be unhaird should first be freed from all impurities by soaking, and then placed so cleansed in the said solution, and allowed to remain in it about a quarter to half an hour according to the kind of leather. The hides are then removed and worked in a fulling trough with water, after which they are ready for tanning. For preserving and disinfecting purposes powdered 'borol' is to be mixed with suitable indifferent substances," such as common salt, Glaubers salt, &c.—H. S. P.

Improvement in the Manufacture of Animal Glue. E. Brand, Rostock, Germany. Eng. Pat. 15,630, August 31, 1892.

THE inventor adds to the glue a mixture of borax and calcined potash, as borax alone is not sufficiently alkaline to kill the corrupting bacteria in the glue gelatin. The process is performed by dissolving 60 kilos. of ground borax in 100 kilos. of boiling water containing 4 kilos. of 90 per cent. calcined potash, and then pouring this into 1,450 kilos. of hot glue liquor showing 12° by the hydrometer. The product so obtained will keep for a long time without developing any obnoxious smell. Printed work when coated over with this glue is rendered more durable, and it will also be found superior to cake glue in the carpet and leather manufacture, also in bookbinding.—L. de K.

XVI.—SUGAR, STARCH, GUM, Etc.

PATENTS.

Improvements in Apparatus for Extracting Juice from Sugar Canes. D. Stewart, Glasgow, Lanark. Eng. Pat. 16,464, September 29, 1891.

IN the subjoined drawing, A is an open vessel supported by pillars B above an upwardly acting hydraulic press C, the plate D, of which is exactly adapted to the flanged bottom edge E of the vessel A; when D is raised it closes A tightly. F is a perforated shell in which the canes are placed vertically, it may have an inner perforated tube G, thus making the space for the canes annular. The shell is run on to the plate D by a truck, or on wheels H and is thence raised by the hydraulic press C into the vessel A. The piston J of the hydraulic press K is then forced down upon the canes, whereby they are crushed and a large portion of the juice expressed. This juice is then drawn by

means of pumps (not shown) connected with the pipe P, into a closed receptacle L, which communicates with the bottom of the vessel A by pipes M and N—preferably by several connecting branches round the circumference of A. After drawing off the expressed juice, the piston J is raised, and water or syrup of suitable strength (preferably hot) is forced through pipes Q and N into A to extract the remaining saccharine matter from the crushed canes. The crushing operation may be repeated if necessary. This improved apparatus thus consists of an inverted vessel, a hydraulic press arranged for closing the bottom of the vessel and lifting up into it a shell or basket containing sugar canes, a piston moved downwards by hydraulic pressure for crushing the canes, a vessel to receive the juice, pipe connections with pumps for producing vacuum, and pipe connections for injecting water or syrup, the parts being combined, and operating as described.—A. R. L.

Improvements in Apparatus for Separating Impurities from Sugar. J. Drummond, Govan, N.B. Eng. Pat. 20,119, November 19, 1891.

A SERIES of perforated plates are arranged horizontally round a vertical revolving axis. At one part of the circuit the sugar is fed on to the plates and the movement takes it under a horizontal bar which regulates the thickness of the mass on the plates. At further stages the sugar is subjected to the action of compressed air and of washing liquors, and is finally deflected off the plate by a scraper into a hopper.

—A. J. K.

Improvements in Centrifugal Machines or Hydro-extractors for Extracting Sugar Juice and for other Purposes. J. C. Mewburn, London. Eng. Pat. 20,142, November 19, 1891.

By a special design a centrifugal machine is constructed which will work continuously and can be filled and emptied without stopping the machine.—A. J. K.

New or Improved Process and Apparatus for Concreting Sugar or Crystallising Saline or other Solutions. W. P. Thompson, Liverpool. From J. A. Morell and W. R. Stringfellow, New Orleans, U.S.A. Eng. Pat. 8336, May 3, 1892.

See under 1., page 895.

XVII.—BREWING, WINES, SPIRITS, Etc.

The Pentosans (Wood-Gum, Xylan, and Araban) of Lignified Fibre. C. Schulze and B. Tollens. *Annalen.* 271, 1892, 55–59.

DRIED brewers' grains were washed successively with 2 per cent. ammonia and water, and dried. A portion was treated with 5 per cent. soda-lye (6 parts) for two days, when a gelatinous mass was obtained, which, when freed from the liquid portion, and washed with alcohol, hydrochloric acid and ether, left 7 per cent. of the original weight of material employed as wood gum of specific rotatory power $[\alpha]_D = -70.11$; this on hydrolysis with dilute sulphuric acid yielded a mixture consisting mostly of xylose, but containing a little arabinose. Another portion of the extracted grains was boiled for six hours with 4 per cent. sulphuric acid when a mixture of xylose and arabinose, similar to that mentioned above, was isolated from the solution; whilst the residue on digestion with soda-lye partially dissolved, and from the solution a brown gum—identical with Hoffmeister's cellulose gum—was obtained. The residue after this treatment was completely soluble in ammoniacal cupric oxide; it was not, however, pure cellulose, but showed, on warming with dilute hydrochloric acid, the presence of pentoses. It is therefore possible, by the above treatment, to dissolve the lignified cells of the grains, and since xylose and arabinose are found to be invariable products of hydrolysis, the presence of the pentosans, xylan and araban, is demonstrated. The complete separation of cellulose and the pentosans was not, however, accomplished, and the authors believe that these compounds exist in combination in the original material. E. Schulze has, indeed, shown (*Zeits. f. physiol. Chem.* 16, 436) that a cellulose containing both dextrose and xylose groups is present, together with lignin proper, in lignified fibre.—A. R. L.

Note on some Conditions under which the Fluorides exert a Maximum Effect in Solutions of Fermentable Matter. J. Effront. *Monit. Scient.* 6, 1892, 81–85.

As the result of further investigations the author finds that acidity is the most important factor that governs the antiseptic action of fluorides on the lactic, butyric, and acetic

ferments. In a neutral or alkaline medium, fluorides and even hydrofluoric acid, have no retarding influence. In fact, the lactic ferment was found to develop in an alkaline or neutral wort, containing as much as 50–100 mgrms. of a soluble fluoride per 100 cc. The antiseptic action only becomes evident in an acid medium, and is proportional to the amount of acid present. An addition of 3–6 mgrms. of a fluoride to ordinary distillery wort suffices to arrest completely the growth of acid ferments; and the dose may be reduced to 0.005 to 1 mgrm. if the wort contain 3 grms. of acid (calculated as H_2SO_4) per litre. Temperature is another factor, although only of secondary importance, the maximum antiseptic effect being obtained at 50° – 60° C.

As regards the action of fluorides on yeast, the chemical composition of the wort plays a most important part. The author has previously shown that the addition of 6 mgrms. of fluoride to a pure cane-sugar fermentation renders the yeast perfectly inert. In the case of malt wort this experience is completely reversed, a distinct increase in the fermentative and reproductive power of the yeast being observed. This difference in behaviour was eventually found to be due to the phosphates, particularly potassium phosphate, always present in wort. Experiments illustrating this fact were made with molasses. Similar results were obtained when pure yeast was used in the fermentations. The influence of phosphates is less marked when a large excess of yeast is employed. The degree of acidity of a wort when it exceeds a certain limit greatly accentuates the retarding influence of fluorides on yeast. Thus, in a malt wort containing per 100 cc., 540 mgrms. of lactic acid, 0.5 mgrm. of HF produces a distinct effect, whilst in presence of 10 mgrms. fermentation and yeast reproduction are almost completely arrested. In quantities up to 360 mgrms. lactic acid has but little influence. (See this Journal, 1890, 748, 1055; 1892, 50, 626–627.)—H. T. P.

PATENTS.

Improvements relating to the Production and Preservation of Pure Yeast. H. E. Newton, London. From La Société Anonyme "La Levure," Paris. Eng. Pat. 13,088, August 1, 1891.

THE fermenting vessel consists of a closed metallic vessel with the necessary connections, attemperator, &c. Sterilised wort is run in and seeded with a pure cultivation of yeast. Sterilised air is blown through the wort as the fermentation proceeds with the object of increasing the yield of yeast. When the fermentation has ceased, the contents of the vessel are led into a filter, consisting of a conical vessel of perforated sheet iron or wire gauze, and covered with a cloth. The yeast remaining on the cloth is mixed with wort containing 5–15 per cent. gelatin and run into sterilised vessels, which are then sealed and may be kept with unimpaired quality for some time.—A. L. S.

Improvements in the Manufacture of Spirits. H. A. Snelling, London. Eng. Pat. 17,558, October 14, 1891.

THE object is to obtain a spirit with a fine flavour from fermented wort prepared from raw grain.

Before fermentation the wort is mixed with hops, about 10 lb. to every 100 gallons of wort, and the fermented liquor distilled. Before the second distillation, a further amount of 4–5 lb. hops are added to every 100 gallons. The hops are best prepared by first withering in the air for 4–24 hours, and then heated to 240° F. in a "Davidson's sirocco" for 15 minutes.—A. L. S.

Improvements in the Method of and Apparatus for Securing a Continuous Time Record of the Rate of Distillation and Direction of Flow of Distilled Fluids. J. J. McDaniel, Bandon, Co. Cork. Eng. Pat. 17,750, October 16, 1891.

THE condenser discharges into an open receiver, from which pipes lead to the different vessels. The apparatus is so

arranged that the distillate can only escape by one of these pipes at a time. A small open vessel is in communication with each of these pipes, and in it is a float. The movements of the float are communicated by a cord to a pencil, which marks on a rotating cylinder the variations in the height of the float; as this is proportional to the rate of flow from the condenser, a continuous record is thus obtained.—A. L. S.

Improvements in Drying and Calcining Brewers' Refuse and Grains and other Substances and Materials. E. Barlow, Manchester. Eng. Pat. 18,833, October 31, 1891.

THIS is an improvement of the apparatus described in Eng. Pat. 12,535 of 1890, for drying the above-mentioned substances in a rotating cylinder heated in a furnace.

If hot air be supplied to the interior of the cylinder, eaking and burning of the substances are avoided, and a better and more marketable product is obtained.

The air is heated by passing through a tube placed in the upper part of the furnace, and is distributed in the interior of the rotating cylinder by a perforated tube concentric with its axis.—A. L. S.

Improvements in Kilning Malt, and in Structures and Apparatus therefor. R. H. Leaker, Bristol. Eng. Pat. 18,997, November 4, 1891.

THE kiln is very similar to an ordinary malt kiln, and is provided with two floors. The special arrangement is that the heated air after passing through the malt on the lower floor does not pass through the malt on the upper floor, but escapes by a separate flue, and the heated air for the malt on the second floor is conducted from the fire to the malt by a flue, and after passing through the malt escapes through openings in the roof.

The flues are provided with dampers so that either floor may be used separately or both together.—A. L. S.

An Improved Process of Finishing Beer. J. F. Witteman. New York, U.S.A. Eng. Pat. 6531, April 5, 1892.

THE patent relates to the brewing of lager beer. It is proposed to conduct the fermentation under a pressure of air or carbonic acid gas and maintain or increase the pressure until the beer has become brilliant and is racked.

—A. L. S.

Improvements in the Treatment of Hops and their Use in Brewing. B. J. B. Mills, London. From "The Brewing Improvement Company," Maywood, New Jersey, U.S.A. Eng. Pat. 9777, May 23, 1892.

BEFORE using hops in the copper or cask, it is proposed to subject them to the action of dry heat until they are parched. It is claimed that there are many advantages in using hops which have undergone this treatment.—A. L. S.

Improvements in Methods and Apparatus for Carbonating Beer. B. J. B. Mills, London. From "The Universal Carbonating Company," Newark, New Jersey, U.S.A. Eng. Pat. 12,413, July 5, 1892.

THIS relates more particularly to lager beer. The carbonating apparatus consists of a tube through which the beer passes at a pressure of 20 lb. on the square inch, and into which carbonic acid gas is injected. The unabsorbed gas is re-injected into the uncarbonated beer. After filtration the beer is racked at a sufficiently high level to reduce the pressure to 5–8 lb. per square inch.—A. L. S.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

(A.)—CHEMISTRY OF FOODS.

Note on the Optical and Chemical Analysis of Butter. F. Jeun. Monit. Scient. 6, 1892, 91–98.

See under XXIII., page 945.

The Reaction of Milk to Phenolphthalein. L. Vaudin. Bull. Soc. Chim. 7–8, 1892, 283.

THE milk of all the animals that the author has examined is acid to phenolphthalein when fresh. That of the sheep, goat, and cow, is fairly strongly acid; that of the mare, ass, sow, bitch, and woman, is feebly acid. By the former term is meant an acidity corresponding to about 1 or 2 grms. of phosphoric acid per litre, whilst the quantities included in the latter phrase range from 0.1 to 0.4 grm.

The author has also studied the differences in the acidity of the milk of the cow at various periods before and after parturition; he has found that the acidity diminishes to about one-half when the pregnant animal is on the point of ceasing to give milk, and becomes two or three times as great as usual when calving is about to take place. The influence of fodder is small for the same animal. Evening milk is always less acid than that drawn in the morning or at midday. The variations due to differences of breed or of soil are not great. In short, the greatest effect is that due to individual peculiarities.—B. B.

PATENTS.

Improvements in Apparatus for the Manufacture of Butter. N. Rolland and H. Francois, Brussels, Belgium. Eng. Pat. 15,352, September 10, 1891.

THE invention relates to apparatus for butter-making, and provides improved means for the passing of bubbles of purified air through the milk, which will cause the required agitation and the complete separation of the butter.

The apparatus consists essentially of a suitable generator of an air current, such as a fan or blower, a purifying vessel containing a suitable material for filtering the air, and a churn connected with the blower by a pipe which delivers the air into a perforated box placed in the bottom of the churn, and made of two flanged parts riveted or bolted together, the said air escaping from the box and then rising through the milk.

The cylindrical sides of the box are best extended upwards and connected to an outer cylinder, so as to provide an annular chamber communicating, by means of perforations, with the box below and laterally with the liquid within the upwardly extending sides so that the milk is acted upon both in a horizontal and vertical direction. The air purifier is constructed of a cylindrical vessel provided with a cover fastened by means of a catch, so as to renew the wadding. To prevent particles of wadding from entering the air-pipe, the vessel is provided at each side with a nozzle, in front of which is arranged a sieve or grating allowing of the passage of the air.

—L. de K.

Improved Apparatus for the Production of Dry Extract of Coffee or Tea. P. Meyer, Paris, France. Eng. Pat. 17,363, October 12, 1891.

THE process employed is an improvement on the one described in Eng. Pat. 19,882, December 10, 1889. It is now also extended to the manufacture of dry extract of tea.

The process consists essentially in preparing an extract of coffee or tea and flavouring this with the essential oils derived from the roasting of either coffee or tea.—L. de K.

An Improved Blood-forming Substance and Method of Producing the Same. E. R. Kobert, Dorpat, Russia. Eng. Pat. 19,859, November 16, 1891.

THE invention relates to the preparation of a blood-forming medicine superior to iron albuminates, iron peptonates, and homoglobin preparations on account of the greater proportion of available iron which it contains.

Fresh, defibrinated blood suitably diluted with water is mixed with a reducing agent, such as a saturated solution of pyrogallie acid. A voluminous precipitate is obtained, which is washed first with water and then with alcohol. After drying, the preparation is ready for use; it contains 1 per cent. of iron.

It, instead of pyrogallie acid, other reducing agents, such as zinc, iron, and the like, are used, the precipitate must be subjected to a purification so as to remove the last traces of the reagent used. This is best effected by treating it with a saturated solution of sal volatile, and after filtering off from any deposit, it may be reprecipitated by cautious addition of weak hydrochloric acid. It is thus obtained as a brownish-red precipitate, which must be washed with water and then dried over sulphuric acid or calcium chloride.—L. de K.

Improvements in Fodder Cakes. A. J. Boulton, London. From A. W. Rehnström, Mülhammar, Sweden. Eng. Pat. 10,266, May 30, 1892.

THE object of the inventor is to utilise the whey obtained in dairies after the manufacture of cheese, and to obtain therefrom a substantial, wholesome, and fattening food for calves and other young cattle.

After the whey has been reduced to a small bulk by evaporation, it is mixed in varying proportions with linseed cake, maize, rice, peas, beans, or similar foods, to which a little bone-dust may also be added. The commingled ingredients are then made into cakes of suitable form by subjecting them to pressure. To obtain the cakes in a more porous state, the ingredients may be mixed with carbonate of soda and hydrochloric acid. They are formed without being subjected to pressure, and after being baked in an oven they are ready for use.—L. de K.

Improvements in Soluble Chocolate and the Process of Preparing the Same. S. T. Achon, Brooklyn, U.S.A. Eng. Pat. 13,615, July 26, 1892.

THE inventor has improved a composition which is a confection and at the same time a basis to form a chocolate beverage without boiling.

About 1 lb. of chocolate, 1½ lb. of sugar, and 1 pint of cream or condensed milk is heated and made into a thick paste, and finally stiffened by adding more sugar until it can be handled and moulded into pieces of suitable size. The pieces are then immersed in a thick syrup of sugar and water until they are covered with crystallised sugar, when they are taken out and allowed to dry.

This produces a hard close covering of sugar all over the central mass, excluding the air, and so preserving the preparation indefinitely. The cakes readily dissolve in warm water.—L. de K.

Improvements relating to the Production of Cheese. E. G. N. Salenius, Stockholm, Sweden. Eng. Pat. 13,641, July 26, 1892.

THE liquid designed for making cheese, such as skim milk, fatty milk, or cream, is heated to a suitable temperature and introduced into a continuous butter-making machine. Rennet or a suitable acid should be mixed with it either before or after it is put into the apparatus. In the production of fat cheese it is advantageous to agitate the liquid during the centrifugal action, but this is not necessary when meagre cheese is wanted. Colouring agents or flavouring matters may be added in drops or continuously to the liquid during its treatment in the apparatus. The

curd or cheese mixture is finally treated in the ordinary manner to obtain cheese, the curd and the whey having been removed either together or separately.

The apparatus employed has been already described in Eng. Pat. 21,068, December 24, 1890, but the liquid may also be treated or agitated by other means.—L. de K.

(B.)—SANITARY CHEMISTRY.

The Purification of Waste Water from Works by Alumina. Rev. Ind. 23, 386.

THE waters, which remain clear for some days, contain 500 to 800 grms. of fatty matter per cubic metre. If to 1 litre of this liquid is added 1 grm. of alumina, together with 15 to 20 per cent. of water, the solution turns brown, and a precipitate is formed which, when heated to 100° C., leaves a residue weighing 1.6 grm., and containing 30 per cent. of fatty matter. Also, if to a solution of soap in distilled water to which a few drops of hydrochloric acid had been added, a small quantity of alumina be now added, the liquid is instantly cleared with formation of an abundant precipitate.—G. H. R.

Is Magenta Poisonous? P. Cazeneuve. Monit. Scient. August 1892, 557—560.

See under IV., page 900.

PATENTS.

Improvements in or Appertaining to Disinfectants for Water-Closets and other Places or Things where Water is used. H. B. Thornton, Liverpool. Eng. Pat. 13,262, August 5, 1891.

FOR details concerning this invention consult the inventor's later patent (Eng. Pat. 17,421, 1891; this Journal, 1892, 365).—H. T. P.

Improvements in Apparatus for Filtering Polluted Waters and other such Liquids. F. P. Candy, London. Eng. Pat. 16,604, September 30, 1891.

THE special feature in this apparatus is the facility with which the filtering material can be washed. The apparatus consists of a cylindrical vessel provided with a perforated false bottom on which the filtering material rests. A vertical shaft, which can be rotated from the outside, reaches down to the false bottom, and carries at its lower end a number of agitating blades, corresponding baffling arms being attached to the wall of the cylinder. The filtering material, if very light (cork), is pressed down by means of a perforated cover, which can be raised to the top of the cylinder when necessary. The apparatus is constructed to filter downwards. When it is required to cleanse the filtering medium, the perforated cover is raised to the top of the apparatus, a stream of water is introduced below the false bottom, and the central shaft with vanes is caused to rotate. By this means the filtering material is violently stirred up with a large volume of water, resulting in the rapid elimination of all impurities, which escape through the perforated cover and flow off through a pipe near the upper end of the cylinder.—H. T. P.

The Utilisation of a Certain Waste Oxide of Iron in the Purification of Sewage, and for similar Purposes. H. C. Saceré, Pendleton, and H. Grimshaw, Manchester. Eng. Pat. 17,911, October 20, 1891.

ACCORDING to this invention, the ferric hydrate obtained as a waste product in the purification of zinc chloride is utilised for the production of ferric chloride or sulphate. These salts may be employed in the purification of sewage, coal-gas, and for many other purposes.—H. T. P.

An Improved Process for Oxygenating, Deodorising, and Disinfecting Sewage or other Fermentable or Noxious Matters. A. P. Hope, Mayland, Wellingborough, Norths. Eng. Pat. 17,924, October 20, 1891.

THE sewage, &c., is treated in suitable tanks with a current of "antiseptic" steam until deodorised. The antiseptic steam is generated from a solution of 1 gall. of "Bacillite" (composed of cresylic oil, 8 parts; sulphur, $\frac{1}{2}$ part; hydrate of soda, 2 parts; carbonate of soda, 1 part; resin, 2 parts, boiled for 2 hours) or other suitable disinfectant, in 200 galls. of water. This quantity is said to be sufficient to disinfect 4,000 galls of sewage.—H. T. P.

New or Improved Method in Sewage Precipitation. G. C. Purvis, Edinburgh. Eng. Pat. 18,286, October 24, 1891.

THE sewage is charged with sulphur dioxide or carbon dioxide, or a mixture of the two gases, thorough absorption being secured by effecting the treatment in tanks fitted with baffling plates, or by allowing the sewage to trickle over coke, &c., arranged in towers through which a current of the gas ascends. Milk of lime is then added, and also, if desired, small quantities of aluminium and iron salts. Sufficient lime must be employed to precipitate the dissolved gas or gases as insoluble calcium salts, to decompose any iron and aluminium salts added, and finally, to neutralise the acidity (if any) of the sewage. In treating neutral or faintly alkaline sewage of average composition, the following quantities of the different materials may be employed per gallon:— SO_2 , 7.5 grains; CaO , 7.5 grns.; aluminium sulphate, $\text{Al}_2(\text{SO}_4)_3$ 18 H_2O , 4 grns. In addition to the above, 1—5 grns. of finely-powdered charcoal may be added. Excess of lime should be avoided in order that the effluent from the sewage may be as nearly neutral as possible.—H. T. P.

An Improved Preparation for the Alleviation and Cure of Open Wounds, Cuts, Sores, Burns, Scalds, and the like. A. Roth and A. Roth, London. Eng. Pat. 13,277, July 20, 1892.

THE preparation is made as follows:— $\frac{1}{4}$ lb. of rosin and 3 oz. of clarified beef suet are boiled together for a quarter of an hour; 2 oz. of bees'-wax are then added, and the whole is boiled for half an hour more. Subsequently the mixture is allowed to set, when it is ready for use.—H. T. P.

(C.)—DISINFECTANTS.

PATENTS.

An Improved Fluid Insecticide. H. H. Lake, London. From A. G. Pummerer, Wels, Austria. Eng. Pat. 14,788, September 1, 1891.

THE improved insecticide is intended for the destruction of parasites injurious to plants, vines, &c., particularly the *phylloxera vastatrix* and *dispur monacha*. It may also be used against the *peronospora* and other insects. The preparation is made as follows:—The fruit of the horse-chestnut is crushed to paste and digested with several times its own volume of water. The resulting extract mixed with about twice its volume of a resin solution (resin, 3 lb.; soda crystals, 1 lb.; water, 1 pint) forms the insecticide. It may be employed, either as it is, or diluted with water, and is said to have no injurious action on the health of plants.

—H. T. P.

Improved Disinfecting Compound. M. Syer, London. Eng. Pat. 11,049, June 13, 1892.

PERMANGANATE of potash is mixed with plaster of Paris, or other cement or plaster, and cast into bricks, or balls, or into perforated tin cases, the object being to economise the permanganate.—H. T. P.

XIX.—PAPER, PASTEBOARD, Etc.

Residue of Potato-Starch Works as a Material in Paper-Making. W. Herzberg. Mith. Königl. tech. Versuchs, 1892, 124—126.

THE residues of potato-starch works cannot be used as a substitute for cellulose in paper-mills, but may serve as a "filler," the soft parenchyma of the potatoes not possessing sufficient tenacity to yield a good paper felting. A Cologne firm has used large quantities of potato-starch residues, but mostly for the reason that the pulp from white potatoes imparted to the paper a delicate ivory tint or a beautiful pink hue, when coming from red tubers. The author has examined a packing-paper made from wood-cellulose containing 30—40 per cent. of potato-pulp. Its mean "tearing length" was found to be 2.03 kiloms., the mean "elongation at fracture" 1.1 per cent.; the resistance when crumpled and rubbed could hardly be termed "indifferent." A microscopic examination of the paper easily reveals the origin of the filling material.—J. L.

Safety Paper. W. Herzberg. Mith. Königl. tech. Versuchs, 1892, 114—119.

THE author has examined a new safety paper (for cheques, securities, &c.) which had been submitted for approval and adoption to the Austrian Government. The subjoined table contrasts the results of the examination of this new paper with those of a paper used hitherto for that purpose.

—	Mean		Resistance against Crumpling	Material.	Ash.
	Tearing Length.	Elongation at Fracture.			
Old paper	Km. 3.77	Per Cent. 2.6	Moderately great.	Wood cellulose, cotton, linen.	Per Cent. 6.39
New paper	4.58	4.4	Very great	Linen and cotton.*	2.09

—	Thickness.	Weight.	Sizing.	Temperature and Moisture of Air at Time of Testing.	
	Mm.	Grms. Sq. m.		° C.	Per Cent.
Old paper	0.08	57.0	Strong	19.2	65
New paper	0.13	83.3	Not strong.	19.2	65

* The embedded fibres are of tussur silk.

THE new paper, which is characterised by a pinkish hue and the embedded red silk fibres, is, as will be seen, considerably superior to the old paper. The weaker sizing of the former must be considered as an advantage, inasmuch as the ink penetrates more deeply into the paper, and the strokes of the writing cannot be removed so easily. The reddish hue of the paper is due to a colouring matter which is turned blue by the minutest quantity of an acid, and is probably intended as a protection against malpractice with acids, but the reddish tint can be restored by alkali. A second table, for which the original paper must be consulted, gives a number of experiments made with the purpose of removing written characters by erasure or by washing with water, alcohol, hydrochloric acid, caustic soda, chlorine water, oxalic acid, oxalic acid and subsequently chlorine. The author used for these experiments four kinds of writing ink, viz., alizarin, anthracene, aniline, and gallotannic inks. As a general result it may be stated that the new paper proved also in this series of experiments much superior to the old paper. In the second part of his communication the author reviews the previous attempts that have been made by several inventors to produce a safety paper.—J. L.

PATENTS.

Improvements in the Manufacture of Bookbinders' Cloth. T. A. Sutton and W. H. Suttou, Salford. Eng. Pat. 13,148, August 4, 1891.

See under V., page 903.

Improvements in or Relating to Apparatus for Glazing Paper. A. J. Boulton, London. From A. Bachem, A. Vogelsang, and G. Tischer, Dresden. Eng. Pat. 13,322, August 6, 1891.

INSTEAD of glazing paper by passing it between a number of heated rollers, the inventors cause the web of paper to pass continuously between two zinc plates to which great pressure can be applied. In this way the paper is glazed without being subjected to any strain.—E. J. B.

Improvements in the Manufacture or Treatment of Paper for Cheques, Bank Notes, and the like. A. Schlumberger, Paris. Eng. Pat. 14,897, September 3, 1891.

A VARIEGATED or so-called "splash" paper is made by mixing together white and coloured pulps. The colouring may be done either with colours sensitive to acids and chlorine, such as the aniline colours and wood colours, or resistant to such reagents, e.g., indigo, alizarin, or chrome yellow. Such papers are then printed with gummed water-colours containing mordants or caustic substances.—E. J. B.

Improvements in the Manufacture or Treatment of Paper for Bank Notes, Cheques, and the like. A. Schlumberger, Paris. Eng. Pat. 14,973, September 4, 1891.

By this invention cheques or bank-notes are printed on both sides, the printing corresponding exactly, so that by transmitted light only one print is visible. Each print is made in two or more colours arranged in reverse succession, so that by reflected light two or more colours appear, but by transmitted light only one, the latter being that produced by the combination of the separate colours.—E. J. B.

Improvements in Apparatus for Straining Paper Pulp. J. White, Edinburgh. Eng. Pat. 17,022, October 7, 1891.

THIS invention cannot be properly understood without reference to six drawings which accompany the specification, describing an apparatus for imparting an oscillating motion to the vat, &c.—A. G. B.

Improvements in the Treatment of Rhea to obtain Fibre therefrom, and Appliance to be used in such Treatment. F. J. H. Sampson, Sydenham. Eng. Pat. 17,642, October 15, 1891.

RHEA is treated with a boiling solution of carbonate of soda until the gum and resin are in a "slimy, semi-adhesive" condition. The rhea is then removed from the bath and immediately treated with a jet of boiling water and steam, delivered from a nozzle of peculiar construction.—E. J. B.

Improvements in the Manufacture of Vegetable Parchment. J. Robertson, Staines. Eng. Pat. 8473, May 4, 1892.

THE paper is made to pass through a parchmentising bath of sulphuric acid, then through baths of water to remove the excess of acid, and finally through a bath of glycerin.

—E. J. B.

Improvements in and connected with the Manufacture of Celluloid Balls and the like. P. Humeau, Hanover, Germany. Eng. Pat. 10,675, June 4, 1892.

ACCORDING to this invention a number of hemispherical projections are stamped by means of a die in a sheet of celluloid. By means of another die the flat portions of the resulting sheet are removed, leaving the hemispheres ready to be joined into balls.—E. J. B.

A New or Improved Method of Producing Flat-Reliefs for Wall Papers, Decorative Wall Ornaments, and the like. P. Klinka, Berlin. Eng. Pat. 11,357, June 17, 1892.

ON the inside of a mould made of plaster of Paris treated with shellac sheets of blotting paper damped with a weak solution of casein and milk of lime are placed, and pressed into the form of the mould by means of a hard brush. The inside is then filled up with a putty made by mixing flour paste with sawdust and turpentine.—E. J. B.

An Improved Carbon Product. L. S. Langville, Troy, U.S.A. Eng. Pat. 13,847, July 29, 1892.

IN the manufacture of paper pulp from wood or esparto grass and the like, the raw materials are treated with caustic lye, which dissolves the silica and saponifies the resinous substances. The alkaline solution is evaporated to dryness, calcined ("re-carbonised"), and the residue taken up with water. It is proposed to prepare a new form of carbon from this residue, by neutralising the alkali with weak acid, after which the material is dried and powdered. The product so obtained is said to be pure enough and well adapted for electric light carbons.—H. A.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

On Citronellone, an Unsaturated Fatty Aldehyde. E. Kremers. Am. Chem. Journ. 14, 203—207.

THIS paper is a continuation of the author's work read before the American Pharmaceutical Association in 1887, and the prime object of examining the andropogon oils at present must be to study carefully the chemical characteristics of the substances they contain. Since then two chemists have taken up the subject of these oils: Mr. Frank D. Dodge (Am. Chem. Journ. 11, 456; 12, 553), and Dr. F. W. Semmler (Ber. d. chem. Ges. 24, 208), and the discrepancies between the recorded observations are probably due to lack of uniformity in the materials and processes of manufacture employed. The substance which has furnished the subject for this preliminary paper is the so-called citronellon from the oil of *Eucalyptus maculata*, var. *citriodora*, which was isolated from the oil by the chemists of Messrs. Schimmel and Co., Leipzig. The citronellone from this source is a colourless, oily liquid, of a lemon-like odour not at all disagreeable. Its specific gravity is 0.875 at 17.5°, and 0.871 at 20° (0.873 at 15°). It rotates the ray of polarised light to the right 7.127° in a 1-dm. tube. Hence $[\alpha]_D = +9.18^\circ$.

Citronellone and Sodium Acid Sulphite.—The citronellone was separated from the other constituents of the eucalyptus oil by means of its crystallisable sodium acid sulphite compound (Schimmel & Co., "Bericht," October 1890, 21). From this it was regenerated with the aid of sodium carbonate. That the compound had not suffered any change was readily shown by the fact that it again combined with sodium acid sulphite. The observation made by the chemists of Schimmel and Co., that the union of the two compounds is accompanied by a considerable

rise in temperature, can also be confirmed. If molecular quantities of citronellone and sodium acid sulphite are triturated in a mortar the latter will dissolve in the former, and upon the addition of a few drops of water the emulsion-like liquid will congeal. This method of preparing the addition product is not connected with the loss caused by the use of a solution of the sodium acid sulphite. An attempt to add two molecules of sodium acid sulphite failed.

—G. H. R.

The Alkaloids of Certain of the Solanaceæ. O. Hesse. *Annalen*, 1892, **271**, 100—126.

THE author finds that atropine prepared from the pure commercial sulphate (*Pharm. Germ.* 111.) melts at 115.5° , and has a specific rotatory power $[\alpha]_D = -0.4$ ($p = 3.22$; $t = 15^\circ$); whereas Will and Ladenburg believe it to be optically inactive, and Bredig gives its rotatory power as $[\alpha]_D = -1.89$. Atropine sulphate—

is employed for ophthalmic purposes. Of three samples of this salt, which stood the tests of the German Pharmacopœia, two were found to contain hyoscyamine sulphate. Pure atropine sulphate separates on adding ether to its alcoholic solution in lustrous white needles; whilst when it is contaminated with hyoscyamine sulphate dull white crystalline aggregates are precipitated. The anhydrous salt has a specific rotatory power in 2 per cent. aqueous solution at 15° $[\alpha]_D = -8.8$. The platinichloride melts at 197° — 200° , and the aurochloride at 138° .

Hyoscyamine, $C_{17}H_{23}NO_3$, prepared from the seeds of *Hyoscyamus niger* and also from the commercial sulphate forms white needles, melting at 108.5° ; its specific rotatory power in 3 per cent. absolute alcoholic solution at 15° was found to be $[\alpha]_D = -20.3^\circ$. Will gives -21.68 (*Ber.* **21**, 1722). The sulphate crystallises with 2 mols. H_2O , melts at 201° , and the anhydrous salt has a specific rotatory power in 2 per cent. aqueous solution $[\alpha]_D = -28.6$. The platinichloride melts at 206° , and the aurochloride at 159° .

A crystalline alkaloid comes into commerce under the name of *atropinum naturale*; it is prepared from belladonna roots, and most of the samples of commercial atropine sulphate are derived from this alkaloid. The base forms white needles, melts at 109° , and has a specific rotatory power in 2 per cent. absolute alcoholic solution at 15° $[\alpha]_D = -16.2$. An optical analysis of the sulphate, employing the above given constants, showed it to be a mixture of hyoscyamine sulphate 68.2 per cent. and atropine sulphate 31.8 per cent.

Hyosceine was first isolated by Ladenburg from *hyoscyamus niger* (*Annalen*, **206**, 299). The author finds that it has the composition represented by the formula $C_{17}H_{21}NO_3$, and its specific rotatory power in 2 per cent. absolute alcoholic solution at 15° is $[\alpha]_D = -13.7$. When hyosceine is heated with hydrochloric acid or an alkali, *osceine*, $C_{18}H_{23}NO_3$, melting at 104.5° and boiling at 242° , and atropic acid, $C_{17}H_{19}O_3$, are obtained.

The alkaloid obtained by E. Schmidt from *Scopolia atropoides*, and named by him scopolamine (*Apotheker Zeit.* 1890, 30) is identical with hyosceine. The author is in favour of retaining the name hyosceine (compare E. Schmidt, *Archiv. d. Pharm.* **230**, 207).

The remainder of the paper deals with atropamine from belladonna roots (*Annalen*, **261**, 87); belladonnine (*Ber.* **22**, 3183); and apo-atropine, which closely resembles atropamine in its physical characteristics, and those of its derivatives, but is crystalline, whereas atropamine is amorphous. Apo-atropine is obtained by the action of nitric acid on atropine (*Pesci, Ber.* **15**, 530; Ladenburg, *Annalen*, **117**, 102).—A. R. L.

Cincholine and Fluoroline. O. Hesse. *Annalen*, 1892, **271**, 95—100.

CINCHOLINE, $C_{10}H_{21}N$, is a volatile base met with in the preparation of cinchona alkaloids (*Ber.* **15**, 858); it is identical with the base isolated by Weller from paraffin oil (*Ber.* **20**, 2097), and is a highly refractive oil, boiling at 236° — 238° . It is homologous with conine, but appears not

to be poisonous. *Fluoroline*, $C_{12}H_{13}N$, is an oily volatile base obtained by the author in 1887 by the steam distillation of the so-called amorphous alkaloid of Trujillo coca; its solution in water exhibits a strong blue fluorescence. The author has failed to isolate the base from either Trujillo coca or Java coca, using purified solvents as extracting agents, so that its production from Trujillo coca (Gisel, *Pharm. Zeit.*, **36**, 429) was probably due to its presence in the solvent used, viz., brown coal naphtha.—A. R. L.

Oxygen in Glass Manufacture. Eng. and Mining J. **54**, 413.

An Improved Process and Apparatus for the Manufacture of Solid Carbonic Acid (CO₂). C. R. C. Tiebhorne, A. E. Darley, S. Geoghagan, and M. F. Purcell, Dublin. Eng. Pat. 13,684, August 13, 1891.

CARBONIC acid from brewers' vats (this Journal, 1891, 651), or from any suitable source, is liquefied in a series of stage compressors, the liquid cooled down in a surface condenser and admitted in regulated quantities into an expansion chamber. Part of the liquid volatilises here, and in consequence abstracts sufficient heat to cause the remaining part of the liquefied carbonic acid to solidify. The gaseous carbonic acid may be returned to the pumps. The solidifying chamber may be made fixed or moveable; it is provided with a discharging door for the solid carbonic acid, and is coated with non-conducting material. Boxes, bags, or the solidifying chamber itself may be used for transporting the solid carbonic acid.—H. A.

Improvements in the Preparation of Anhydrous Oxide of Barium, or other Substances of Like Properties, for Use in the Separation of Oxygen and Nitrogen of Atmospheric Air. Brins Oxygen Company, Limited, and K. S. Murray, London. Eng. Pat. 17,298, October 10, 1891.

PIECES of fire-clay, pumice stone, or other inert material are saturated with fused barium nitrate at a high temperature, which is maintained for some time to drive off volatile impurities. The pieces are allowed to cool in an air-tight chamber. The barium oxide so produced presents a large surface for subsequent action on air.—H. A.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

PATENTS.

Improvements in Apparatus for Washing Photographic Prints and Negatives. H. Holcroft, Wolverhampton. Eng. Pat. 19,706, November 13, 1891.

THE improved apparatus consists in a cistern in which is fitted a carrier, provided with narrow ledges or corrugations to receive horizontal trays, upon which the negatives or prints to be washed are placed, the carrier is made somewhat shorter than the cistern in order to leave a water space at each end. The trays consist in frames on which a netting is strung. To prevent prints being washed out of the trays, vertical bars are fixed across the outflow end of the carrier, the ends of the trays being notched to correspond. Water is allowed to drip into one end of the cistern, flows over the surface of the prints or negatives, and escapes by an overflow.—J. C. C.

The Use of Aromatic Amido-Compounds and of the Derivatives of Pyrogallol for the Development of Photographic Images. J. Hauff, Stuttgart, Germany. Eng. Pat. 20,690, November 27, 1891.

THE inventor claims the use of the glycines of various amidophenols, which are readily soluble in alkaline carbonates, for developing photographic images, such compounds having the typical formula—

As an example of a developing solution the following is given—

- 100 cc. of water.
- 4.5 grms. of crystallised sulphite of soda.
- 1.5 grms. of glycine.
- 2.5 grms. of potash.—J. C. C.

Improvements in the Art of Producing Coloured Photographs. J. W. McDonough, Chicago, U.S.A. Eng. Pat. 5597, March 22, 1892.

THIS invention may be carried out in several ways, one being as follows:—A glass plate is coated with varnish, which will dry tacky. Coloured particles, consisting of resin or shellac, stained by aniline dyes, &c., are mixed and dusted on the surface. If these coloured particles are mixed in the right proportion, the plate will "reflect or transmit a mixture of these colours, which will be white in proportion to the purity of the colours, cleanliness of the mixture, and the quantity of light." The plate is then heated just sufficiently to melt the shellac. After sensitising in the usual manner it is exposed in the camera, developed and fixed, a coloured photograph resulting.—J. C. C.

Improvements in Magnesium Flash-Light Apparatus. H. J. Haddan, London. From E. Beste, Weimar, Germany. Eng. Pat. 5996, March 28, 1892.

See under II., page 899.

Improvements in the Method and Apparatus for Producing Magnesium Flash Light. N. Browne. From E. Wünsche, Dresden, Germany. Eng. Pat. 6269, March 31, 1892.

See under II., page 899.

An Improved Developing Tray or Dish for Photographic Purposes. A. Desboutin, London. Eng. Pat. 10,023, May 26, 1892.

THIS is a dish in which negatives may be developed in the ordinary light. A sheet of glass of a nonactinic colour is inserted in the bottom of the dish, and a closely-fitting lid, also fitted with a coloured glass, is provided. At one end there is a spout, across which a screen is placed, to prevent access of light to the interior.

In using, the negative is transferred to the dish and the lid replaced by means of a changing bag; the developing solution is then poured in by means of the spout; after the necessary time the solution is poured off, and the negative may be examined by holding the dish up to a candle or lamp.—J. C. C.

Improved Combined Substances for the Development of Photographic Images. J. Hauff, Stuttgart, Germany. Eng. Pat. 14,542, August 11, 1892.

THE inventor claims the employment of ortho-paradiamido-ortho-cresol and ortho-paradiamidometa-cresol in combination with soluble sulphites for developing photographic images, and gives an example—

- 100 cc. of water.
- 0.5 grms. of diamidocresol.
- 5 grms. of the crystallised sulphite of an alkali.

—J. C. C.

XXII.—EXPLOSIVES, MATCHES, Etc.

Substitutions in Groups Linked to Carbon and to Nitrogen. Application to Explosives. C. Matignon. Compt. rend. 114, 1197—1199.

BERTHELOT has shown that the replacement of an atom of hydrogen by an alcoholic radicle increases the heat of combustion of the body by about 155 cal. for each CH_3 substituted. The author has recently found that the substitution of an alcoholic radicle linked to nitrogen increases the heat of combustion to a greater extent than when the same radicle is linked to carbon.

In the case of methyl linked to nitrogen the heat of combustion is from 163—165 cal., being an increase of 8 to 9 cal.

Hitherto the nitro-compounds with the NO_2 group linked to carbon have only been studied, and the heat of formation of these mononitro bodies corresponds to 36 cal.

The author has thermally studied Guanidine

and its mononitro derivative, in which the group NO_2 is necessarily linked to nitrogen, and finds that the formation of nitroguanidine liberates 30.3 cal. less than when the NO_2 is linked to carbon, consequently the same law holds good as in the case of alcoholic substitutions, viz. that the introduction of the NO_2 group linked to nitrogen increases the heat of combustion of the body by a larger amount than when the NO_2 is linked to carbon.

This has an interesting bearing on explosives, for the nitro-derivatives linked to nitrogen set free 6 cal. less in their formation by nitric acid than those linked to carbon, consequently they preserve the equivalent of the 6 cal. in the form of potential energy which is transformed into sensible energy at the moment of explosion, and consequently the explosive is more powerful when the NO_2 group is linked to nitrogen. Mononitro-guanidine is an energetic explosive and behaves similarly to gun-cotton when heated.

—W. M.

Jute as a Substitute for Gun-Cotton. O. Muhlhaus-cr. Dingl. Polyt. J. 283, 1892, 48—92, 137—140.

THE crude fibrous material is placed in a solution of caustic soda of 1 per cent. strength; gently heated for two hours; allowed to stand for 12 hours; and finally well rinsed with water. Then the treatment with caustic soda is repeated, the object being to obtain the cellulose as free as possible from foreign matters, &c. Afterwards the fibres are immersed in a mixture consisting of 1 part of nitric acid (of 1.5 sp. gr.) and of 1 to 3 parts of concentrated sulphuric acid. As a result of this immersion the fibres turn brownish-red, and are soon disintegrated into many small hair-like parts which probably represent single cells. These are collected, filtered, washed, and dried, after which they appear as a yellowish fibrous material which is analogous to gun-cotton in all its properties. The author is of opinion that for certain special purposes this "gun-jute" will be able to compete successfully with gun-cotton.—H. S.

Methods Employed for Testing Explosive Substances. P. Vieille. Compt. rend. de l'Assoc. Franç. pour l'Avancem. des Sc. 1890, 53; Proc. Inst. Civil Eng. 107, 124—125.

UNTIL about 20 years ago our knowledge of explosives was very limited, and it has only lately been possible to study explosive phenomena in detail. Delicate chronographic methods have had to be devised registering hundred-thousandths of a second, and apparatus had to be

constructed to withstand pressures of several thousand atmospheres. During combustion the amount of heat produced by various explosives differs greatly; for instance, a platinum wire, which is not fused in the flame produced by burning gun-cotton, melts readily when brought into contact with the flame of blasting gelatin.

The volume of gas produced by the decomposition of explosives is very great. Explosives such as gun-cotton or nitro-glycerol produce gas measuring 1,000 to 1,500 times the volume of the original explosive when reduced to ordinary temperature and atmospheric pressure. At the moment of explosion, however, these gases are heated to a temperature of 2,000 to 3,000°, and therefore occupy a space 10,000 to 15,000 times as great as the explosive from which they are derived. The pressures due to this sudden disengagement of gas are enormous, and it is the utilisation of these pressures for blasting and military purposes which determines the value of each explosive. The theoretical pressure which can be developed by an explosive may be calculated from its chemical composition, but the actual pressure produced can also be ascertained by direct measurement. The most simple method of carrying out the latter operation is to explode a charge of the substance to be tested in a closed space with which a crusher-gauge is connected. The crusher-gauge consists of a piston actuated by the force of the explosion and compressing a small cylinder of copper. The amount of compression of the copper cylinder indicates the force which has been developed. The crusher-gauge is usually fixed in one end of a steel tube. The other end is closed, and the charge of explosive is ignited by means of a platinum wire rendered incandescent by an electric current. After the gases produced by the explosion have cooled, the tube is opened and the copper cylinder removed and measured. The amount of compression produced by a known force having previously been ascertained by direct experiment, it is possible to calculate the pressure of the gases which acted upon the test cylinder.

Numerous experiments made with different explosives have shown that gun-cotton, nitro-glycerol, and melinite are the most powerful explosives at present known. The pressures produced by them are three to four times as great as those attained by black powder, and theoretical considerations render it improbable that any more powerful combinations can be produced. The pressure increases very rapidly in proportion to the increase of the charge, so that the strength of the apparatus fixes a practical limit to the records obtainable. The greatest pressures produced are when the explosives completely fills the cavity in which explosion takes place. With gun-cotton a cavity of 1 litre capacity will contain about 1 kilo. of explosive, while the same space will take 1,600 grms. of nitro-glycerol.

In order to ascertain the duration of the explosive action, the author has constructed a registering crusher-gauge, of which an illustration accompanies the paper. A steel point is fixed to the steel piston or plug, which compresses the copper cylinder, and which is itself actuated by the explosion of the substance under examination. This steel point rests upon a sheet of blackened paper, which is rolled round a revolving cylinder. At the moment of explosion the point follows the crusher-piston in proportion as the copper cylinder is flattened by the pressure of the gases, and a line is described upon the paper. A comparison of the lines thus obtained from different explosives shows the rate at which the pressure increases in each case. The speed of the paper is about 10 metres per second, each thousandth of a second being represented by a length of one centimetre.

By means of this apparatus it has been found that not only the duration, but also the manner of combustion varies greatly. In some cases the rise of pressure is very gentle at the commencement and increases suddenly towards the end of the explosion, while with other substances the reverse is the case. With some explosives, such as gun-cotton and nitro-glycerol, the application of fire alone does not produce an explosive action; for these substances a detonator containing fulminate of mercury is used to initiate the explosive wave. In a tube filled with nitro-glycerol the explosive wave travels at the rate of about 1,000 metres a second, but in its more porous form of dynamite this

substance propagates the explosion at the rate of 3,000 to 4,000 metres a second. With gun-cotton the speed is 5,000 to 6,000 metres.

In firearms, where explosives are used as the motive-power, it is necessary to diminish the velocity of explosion in order to avoid too great a strain upon the metal of which the weapon is constructed.

It is in these cases especially that the apparatus described by the author has been found of great assistance.—W. S.

Coal-Dust Explosions at the Zänckerode Colliery, Max Georgi. *Jahrb. für das Berg-und Hüttenw. in Königr. Sachsen*, 1891, 1; *Proc. Inst. Civil Eng.* 108, 77—78.

THE seam, 3 to 5 yards in thickness, worked at the Zänckerode colliery in Saxony, yields a dust of the class described by Atkinson as especially dangerous. Fortunately the dust is present only in small quantities. Three explosions, however, that have recently occurred, show that under certain conditions this dust may be a source of danger. The methods adopted in order to obviate its disastrous consequences, consist in the employment of flameless explosives, and of appliances for artificially moistening the dust by means of a water-spray.

The flameless explosives in practical use are flameless dynamite (*Wetterdynamit*), roburite, securite and carbonite. The first of these contains, as aqueous salt, magnesium sulphate. The best results with this class of explosive were obtained with flameless kieselsguhr dynamite with 40 to 45 per cent. of nitroglycerol. Experience showed, however, that all flameless dynamites deteriorated with keeping, and all evolved noxious gases. Roburite was found to be uncertain in its action, and it was thought to be not homogeneous, or to be subject to spontaneous decomposition. The use of roburite and of flameless dynamite has been abandoned at Zänckerode; but satisfactory results have been obtained with securite and with carbonite. The latest form of carbonite is a nitroglycerol explosive mixed with a sufficient quantity of carbonaceous matter to prevent the formation of free oxygen or of carbonic oxide. Securite consists, so far as is known, of nitrobenzene and ammonium nitrate. With reference to the storing of these explosives, the same precautions must be taken with carbonite as with gelatin-dynamite. Securite, however, is not affected by changes of temperature, but is very sensitive to the action of moisture. Carbonite can be completely exploded by a detonator with a charge of 0.8 grm. whilst securite requires 1.5 grm. The former is found to act best in coal and in soft rocks, and experience at Zänckerode tends to show that it may be used as a substitute for blasting powder in most collieries, and that it must eventually entirely replace dynamite, which is still used here and there. Securite, as a more powerful explosive, is not adapted for soft coal. Its use is, therefore, confined to hard pyritic coal or to hard rock. The amount of coal got by the miner is less with carbonite than with powder; but in narrow headways the length driven is not affected by the use of flameless explosives. The cost of blasting is in all cases higher than when powder is used.

The second method of obviating coal-dust explosions consists in the employment of appliances for moistening the dust. The installation of pipes was begun in May 1890 in the workings in the vicinity of the Carola shaft, where the air is driest and the dust, as is proved by the explosion that occurred there, most dangerous. The water was taken from a drainage level some 270 feet above the workings in question, and an ample supply was available. With the exception of the east-iron mains, all the pipes are of galvanised wrought iron. The use of the spray, the construction of which is shown in drawings accompanying the paper, is confined to the actual workings. The installation extends to sixty working places, and cost 1,700l.—W. S.

Explosive and Ordnance Material. Stephen H. Emmens. Proc. of the U.S. Naval Inst. 1891, 355; Proc. Inst. Civil Eng. 108, 113—115.

THE explosion of what is known as dynamite No. 1, containing 75 per cent. of nitroglycerol, is found to be more effective than that of pure nitroglycerol itself. The author explains this apparent anomaly by what he calls a ballistic theory of explosives.

He calculates the pressure which would be exerted upon the walls of a shell containing the explosive, which pressure represents the aggregate of the impacts of the gaseous molecules, and is directly proportional to the *vis viva* of the mean molecular movements. But since *vis viva* is composed of two factors, mass and velocity, the determination of gaseous pressure alone fails to indicate the character of the blows by which it is produced. It tells nothing as to whether the walls of the containing vessel have to withstand the shock of heavy molecules moving with comparative slowness or of light molecules moving at relatively high velocity. The author shows that although the pressure upon the walls of the shell is greater in the case of nitroglycerol, both the intensity and velocity of the blows delivered by the dynamite molecules are greater than those of the nitroglycerol, and the ballistic effect obtained in this manner by calculation is in accordance with that found by experiment.

The author describes a method of testing explosives employed by him, which is as follows: A segment of a sphere of lead is suspended in the air with the convex side uppermost. To the flat base is attached a charge of the explosive to be tested contained in a cylindrical cartridge case of paraffined paper, the lead and the cartridge being thus in the form of a mushroom.

The effect is measured by the amount of indentation produced. The metal is scarred and pitted in such a manner as to show that there is no approach to uniformity of pressure produced by the explosion, the gas molecules appearing to strike the lead like a charge of small shot.

When a cannon ball is driven along the bore of a gun by the impact of a column of gas, the pressure sustained by the walls of the gun is much less than that exerted on the base of the shot. The column of gas must be considered as a stream of minute projectiles darting onwards with a common movement of translation and not darting in every direction as in a vessel filled with gas. For utilising high explosives in firearms and ordnance, the author constructs cartridges lined with soft wood. The lining protects the metal of the gun against a disintegrating shock, and by its resilience enables the gaseous molecules to retain their energy in the form of motion and to gradually join the onflowing current along the bore of the gun.

The author gives tables of the comparative strength of different explosive compounds, his method being to first determine how much heat is set free by the re-arrangement of the molecules after deduction of the heat absorbed in breaking up the explosive to start with, obtaining in this way a measure of the total mechanical force rendered available. He then considers the mode in which the explosive develops its strength—whether by a large volume of gas at comparatively low temperature or by a small volume highly heated, and is then in a position to discriminate as to the particular use for which any explosive is adapted. There follows a description of the composition and method of manufacture of a number of so-called smokeless powders, and among them Emmensite and Gelbite, invented and manufactured by himself, together with an account of experiments made upon them in the United States. The article concludes with an account of tests made with different alloys of aluminium bronze, with a view of ascertaining the behaviour of the material under conditions of sudden stress.—W. S.

PATENTS.

Improvements in Fireworks. C. Huelser, London. From G. Gillischewsky, Berlin. Eng. Pat. 18,439, October 27, 1891.

TWELVE parts of steel chips are first dipped into a solution of stearin and benzine in order to coat them with stearin. These coated chips, along with 96 parts of lead nitrate and 12 parts of charcoal, are introduced into an alcoholic solution of shellac. Wooden matches are then dipped into this viscous mass and can be used for producing star fireworks.—W. M.

An Improvement in the Manufacture of Pyroxylines. H. de Chardonnet, Paris. Eng. Pat. 19,560, November 11, 1891.

THIS invention consists in the preparatory treatment of the cellulose material intended for nitration, by heating it for several hours to 150° to 170° C. The application of this high temperature is said to increase the solubility of the subsequently formed pyroxylines.—W. M.

Improvements in the Means for Blasting by Explosives. F. Pfeiffer, Goslar am Harz, Germany. Eng. Pat. 11,753, June 23, 1892.

ACCORDING to this invention the explosive is placed at the bottom of the bore-hole, and water contained in a vessel open at top and fitting the bore-hole is placed in the same. The bore-hole and water vessel are then closed at top by a priming cartridge, the explosion of which causes the explosion of the charge at the bottom of the hole.

The cartridge may also be provided with an additional compartment for containing water or other flame-preventive for use in firing mines.—W. M.

Improvements in Explosive Compounds. H. J. Allison, London. From A. C. Rand, New York. Eng. Pat. 12,744, July 12, 1892.

NITROBENZENE, or the light oil of coal tar, nitrated to have a specific gravity of 24° to 34° B., is incorporated with potassium chlorate in the proportion of one part of the former to four of the latter. Instead of pure potassium chlorate equal parts by weight of this substance and manganese dioxide may be mixed with 15 per cent. of nitrobenzene or 60 per cent. of potassium chlorate and 40 per cent. of an inert substance mixed with 15 per cent. of nitrobenzene also forms an effective explosive.—W. M.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS.

Apparatus for Extracting Liquids and Pulpy Substances. Holde. Mitth. Königl. techn. Versuchs 1892, 130—132.

THE working of the apparatus will be easily understood by a glance at the annexed sketch. The substance to be extracted must, of course, be at a sufficient depth below the siphon *a*, so as to prevent the possibility of any particles of the substances being conveyed into the flask *A*. Whilst extracting fats emulsified by soap solutions, the author found that air bubbles rising from the bottom of the soap solution were apt to carry along with them parts of the solution into the ether and therefrom into the flask *A*. An

APPARATUS FOR EXTRACTING LIQUIDS AND POLY-
SUBSTANCES.

addition, however, of an easily-soluble salt, as potassium sulphate, did away with this defect of the apparatus.—J. L.

A Simple Apparatus for Evaporating under Diminished Pressure. C. Schulze and B. Tollens. *Annalen* 1892, 271, 46—48.

THE purpose of the apparatus, shown in the Figure, which is similar in principle to Yaryan's vacuum evaporating apparatus (this Journal 1888, 313) devised for the purposes of the sugar industry, is to obviate the long exposure of a solution during its evaporation under diminished pressure, to a high temperature, whereby in some cases decomposition occurs. It consists of a copper tube of 3 cm. inner diameter, bent in the form of a worm, and heated in a water-bath. The liquid to be evaporated is drawn through this tube by means of a water-pump *e*, which latter also serves to maintain a partial vacuum within the apparatus. A piece of wide glass tubing is fixed in the upper end of the copper tube by a perforated rubber stopper, and a narrower glass tube drawn out to a point and provided with a tap to regulate the rate at which the liquid is introduced, is fixed, also with a perforated rubber stopper, into the larger tube. The lower end of the copper tube, which projects beyond the bath, is somewhat narrower than the other portion, and it is attached to a glass tube, which is fused to a bulb at *b*, and connected with a condenser *c*. The concentrated solution falls into the flask *f*, and may be removed by means of the siphon, after admitting air into the flask; whilst the condensed steam is collected in the flask *d*, the uncondensed steam being carried off by the pump. By means of the apparatus 4—5 litres of a dilute solution may be concentrated to 1 litre in the course of an hour.—A. R. L.

SCHULZE AND TOLLENS' APPARATUS FOR EVAPORATING UNDER DIMINISHED PRESSURE.

INORGANIC CHEMISTRY.— QUANTITATIVE.

New Method for the Separation of Iron from other Elements. T. W. Rothe. *Mith. König. tech. Versuchs.* 1892, 132—142.

THE author bases his new method on the solubility of ferric chloride in ether, in which the chlorides of other metals that usually occur in steel are insoluble. The solutions from which the iron is to be extracted must be strongly acid. For convenient extraction, the author has designed an apparatus the main feature of which consists in two cylindrical extractors being connected at the bottom by means of

a three-way tap, which allows of their being brought into communication as well as their being emptied separately. During the shaking out the top parts of the cylinders are also closed by taps. The conditions for a correct determination of the iron are the following:—(a) Suspended substances as, *e.g.*, silica, carbon, fibres of filter-paper, must not be present; (b) the hydrochloric acid solution must contain the iron in the ferric state only; (c) excess of chlorine, nitric acid, and other ether-decomposing substances must be removed; (d) the quantity of a hydrochloric acid present must be so large that the extracted liquid contains 21—22 per cent. HCl (*i.e.*, has the sp. gr. 1.100—1.105 at 13°C.). The author proceeds in the analysis of steel as

follows: 5 grms. are dissolved in hydrochloric acid and the silica separated as usual. The solution of iron is evaporated down, until hydrochloric acid vapours escape, and oxidised with 2-2.5 cc. nitric acid of 1.4 sp. gr., and finally boiled down until basic iron chloride separates. The residue having a volume of about 10 cc. is transferred into the extractor and 55-60 cc. hydrochloric acid, 1.124 (at 19° C.), are added. Two extractions with ether are sufficient to bring the iron into the ether. Minute quantities of copper and cobalt, which sometimes pass into the ether along with the iron, are easily removed by subsequent washing of the ethereal layer with 10 cc. of hydrochloric acid, 1.101 sp. gr. The author has used this new method in the analysis of more than a hundred samples of steel, iron, and ferro-manganese with satisfactory results.—J. L.

A New Method of Assay of Antimony Ores. A. Carnot. *Annales des Mines*, 1, 1892, 303; *Proc. Inst. Civil Eng.* 110 (iv.), 52.

THE ordinary dry way of assaying antimony ore by fusion with soda charcoal and metallic iron, gives a very inaccurate idea of its metallic contents, the author having found differences from the results obtained by analysis which are rarely below 8 or 10 per cent., and in the case of poor minerals may be as high as 20 or 30 per cent. The author has abandoned the dry method of assay, and now substitutes a method of solution and precipitation of the metal by tin, which gives very satisfactory results. In dealing with sulphide ores, from 2 to 5 grms. of the finely powdered mineral are heated with 50 to 60 cubic centimetres of strong hydrochloric acid, but not allowed to boil. When the action ceases the liquid is decanted, and fresh acid is added until the sulphide is entirely decomposed, a few drops of nitric acid being sometimes added towards the end, and the insoluble matter is washed clean with water. The several acid solutions are united, diluted with an equal volume of water, heated to 80° or 90°, and a plate of tin is inserted. The precipitation of the antimony commences at once, and is completed, when the quantity is about 1 gm., in one and a half hours. The precipitated metal is washed by decantation, digested with weak hydrochloric acid to remove tin salts, and is finally collected on a tared filter, washed with water and alcohol, dried at 100°, and weighed. The error of the result, as determined by experiments upon mixtures of native sulphide of antimony and quartz, is below 1 per cent. on the amount found by more exact analytical methods.

In the assay of oxidised ores which are usually mixed with unchanged sulphide, there is often considerable difficulty in getting the antimony completely dissolved, and there is a further chance of loss by volatilisation. This may be avoided by converting the oxidised minerals into sulphide by passing a current of dry sulphuretted hydrogen through it. This is done by exposing about 5 grms. of the mineral forming a thin layer in a flat-bottomed flask, to the action of sulphuretted hydrogen dried by chloride of calcium, which is introduced through a bent tube nearly touching the layer of mineral. The flask is placed on a piece of wire gauze about 2 in. above the flame of a Bunsen star burner, so that the temperature may not exceed 300°. The gas first reduces the oxide and then converts it into sulphide, a small quantity of oxide and sulphur being produced, which condenses in the cooler part of the flask, but there is no loss of sulphide of antimony. The operation is complete in about an hour, and the solution is effected in the manner described above.

Iron and zinc have no effect upon the accuracy of the result; but when the ore contains lead, that metal is partly precipitated as chloride, while part remains in the rotunda, and is deposited in the metallic state upon the plate of tin. This may be estimated in the weighed metallic precipitate by heating it to 50° or 60° in a solution of sodium persulphide (formed by boiling sodium monosulphide with flowers of sulphur) when the antimony is rapidly dissolved, leaving a residue of lead sulphide containing 86 per cent. of lead. As, however, there is invariably some oxidation during the drying of the precipitate, the surcharge will be somewhat

greater, and 90 per cent. of the weight of the sulphide may be taken to be the proper correction to be made for the lead present. Arsenic, when present in the ore, is precipitated with the antimony, and its presence can be determined qualitatively, but no method of estimating the quantity has been devised. This, however, is of less importance, as arsenical antimony ores are comparatively rare.—W. S.

ORGANIC CHEMISTRY.—QUANTITATIVE.

Viscosity at Low Temperatures (Kältebeständigkeit) of Black Mineral Oils. Holde. *Mitth. Königl. tech. Versuchs*, 1892, 126-130.

THE author states that the test prescribed by the rules of the German State Railways, viz., that in which the criterion is the number of mm. an oil will rise in a U-tube of 5 mm. diameter, under an air pressure represented by 50 mm. water at a temperature of -5° C., or -15° C., during one minute, may lead to discordant results for one and the same oil even when repeatedly tested the same day. The discrepancies are due to the fact that at the low temperature solid particles of paraffin, &c., separate out which do not redissolve when the oil is allowed to assume the ordinary temperature.—J. L.

Analysis of Commercial Yolk of Egg. F. Jean. *Monit. Scient.* 6, August 1892, 561-563.

FOR the dressing of hides in the tawing process, a large quantity of salted yolks of eggs is used, unmixed or mixed with borax for preserving purposes. This material, commanding a high price and being of variable composition, it follows that the method of analysis adopted offers considerable interest.

The method adopted is as follows:—

Determination of the Water.—After having thoroughly mixed the sample, a crucible (which can be connected with a small agitator) is tared, and 10 grms. of the material are weighed out, a few drops of acetic acid added, and the whole is well mixed by means of the agitator. The acidified yolk is now dried very slowly, at first at a temperature of 50° to 60° C. (taking care to stir up the mass with the agitator gradually as the substance dries). The drying process is completed at 110°, and the crucible and contents are weighed with due precautions. The loss by drying $\times 10$ = percentage of water. The difference from 100 = dry extract.

Determination of the Fatty Matter.—The extract is carefully removed from the crucible, pulverised, and extracted hot with petroleum spirit. When the extraction is finished, the spirit is removed by distillation, the fatty matter transferred to a tared crucible, dried for one hour at 110° to 115° C., and weighed. The fatty matter thus found = G.

Vitellin.—By passing into the extractor a current of air, the exhausted material is freed from the spirit it contained, and then it is extracted in the same apparatus, after thus replacing the petroleum spirit by distilled water. The aqueous extract evaporated in a crucible, and then dried at 110° C., gives the extractive matter soluble in water, from which the weight of sodium chloride and of other salts which might have been added to the yolk for preservative purposes, has to be deducted.

Ash.—Into a tared platinum crucible 10 grms. of the yolk are introduced, dried, and then calcined at a moderately low temperature, until white ash remains. This residue is weighed.

When testing salted yolk of egg the attainment of white ash is difficult, for if the temperature be raised too much some sodium chloride may be volatilised and lost. To avoid this, carbonisation should be conducted at a low temperature. The char is then treated in the crucible with hot water, taking care not to fracture the carbonised mass, and the aqueous saline solution is collected. The exhausted charcoal is then calcined until white ash alone is left. The

wash-water from the charcoal is then added to the contents of the crucible. The solution is then evaporated and dried at 110°, the ash weighed, and estimated.

In the presence of the boric acid it is difficult to avoid a loss of sodium chloride during calcination, hence preference is given to the weighing of the NaCl not derived from the ash, but by means of a new test.

It was found that the NaCl increases the solubility of the vitellin in water, and that with the salted yolk an extract precipitated by tannic acid in a much higher degree is obtained than is the case with unsalted yolks. As the dissolved albuminoid matter also makes filtration very difficult, the aqueous extract destined for treatment for the estimation of NaCl is first precipitated with a little tannic acid, then filtered and reduced to a definite volume, and the NaCl is determined in this by precipitation with nitrate of silver.

In another portion of the solution the sulphates are determined, also boric acid, nitrates, salicylic acid, &c.

Knowing the amount of water, fatty matter, ash, and the extract soluble in water, there is obtained by difference the amount of the *insoluble vitellin*.

In order to determine exactly the proportions of the different substances contained in the pure yolk, three samples of pure yolk were prepared, which were analysed separately by the method just described.

From the mean of these three analyses were calculated the following factors:—

	Per Cent.
Water and normal ash.....	54.0
Water	52.6
Extract.....	46.0
Fatty matter (G).....	28.0
Vitellin V (including the extract by water)	18.0
Ratio of fatty matter to Vitellin $\frac{G}{V}$	1.5
100 per cent. reduced extract = G = 60 V.....	40.0
100 per cent. reduced extract.....	2.91 normal.

With these data the composition of the yolk of commerce may be found. If, for example, a sample analysis be taken which gives the following results:—

Water.....	50.76
Ashes.....	15.13
Fatty matters ..	19.78
Vitellin	1.46
Normal ashes	1.112
Sodium chloride	13.080
Boric acid, &c.	0.938

Reduced extract 100—(50.76 + 15.13) = 34.11, giving—

G	19.78
V	14.34

The ratio $\frac{G}{V} = 1.375$ instead of 1.5 is abnormal, because for 100 of reduced extract it gives—

G	57.9
V	42.0
instead of $\frac{G}{V}$	
G	60.0
V	40.0

Calculation of the Quantity of Pure Yolk.—The oil obtained from this sample gives with the oleorefractometer + 14 as pure oil. Knowing that 28 G = 100 pure yolk, the content of pure yolk can be calculated, according to the content of the fatty matter G, by means of the formula $\frac{100 \times G}{28}$, i.e., in the example given, $\frac{100 \times 19.78}{28} = 70.6$ for 100 of pure yolk.

Calculation of Albumen in excess.—For calculating this the amount of vitellin is sought that should correspond to the fatty matter found by analysis, supposing the yolk were pure.

Knowing that 28 G = 18 V we would have $\frac{18 \times G}{28} = V$ which means in the present example $\frac{18 \times 19.78}{28} = 12.70$ V

In the analysis there was obtained	V	14.33
And by the calculation according to G.....	V	12.70
Difference.....		1.63

This difference therefore represents the albumen in excess.

If other matters had been added to the yolk they would be found by means of the same calculation.

Knowing the quantity of pure yolk, the albumen in excess and the ash by difference is found the *added water*, and the composition of the analysed yolk could be formulated in the following way:—

	Per Cent.
Pure yolk.....	70.6
Albumen	1.63
Added salts	14.01
Added water.....	13.76

Control of the Quantity of added water.—Knowing that in the pure yolk at 28 per cent. of fatty matters, G corresponds to 52.6 of water, and that the analysed sample contains 50.76 per cent. of water, the formula, $\frac{52.6 \times G}{28}$ is calculated, i.e., $\frac{52.6 \times 19.78}{28} = 37$ per cent. 10 per cent. normal water.

We have therefore—

	Per Cent.
Total water.....	50.76
Normal water	37.10
Added water	13.66

Applying these calculations to the case of samples which have given the following results by analysis:—

Determined Matters.	A.	B.	C.	D.	E.
Water.....	58.84	48.910	52.034	46.60	50.76
Ash	18.50	17.468	18.740	16.91	15.13
Oil.....	14.23	18.840	15.550	18.52	19.78
Vitellin	14.23	13.840	11.460	13.78	12.87
Extract	10.34	0.942	1.556	1.24	1.46
	100.00	100.000	100.600	100.00	100.00

Saline Matters.	A.	B.	C.	D.	E.
Normal ash	1.10	1.112	1.07	1.112	1.112
Sodium chloride..	16.71	14.850	17.80	14.420	13.080
Boric acid, &c. ...	0.78	1.500	17.80	1.478	0.938

	Proportion $\frac{G}{V}$				
—	A.	B.	C.	D.	E.
Pure yolk	1.37	1.29	1.19	1.23	1.37

The following compositions are obtained:—

—	A.	B.	C.	D.	E.
Pure yolk	Per Cent. 50.780	Per Cent. 67.000	Per Cent. 55.00	Per Cent. 65.00	Per Cent. 70.00

Estimation of Nitrogen in Inorganic and Ethereal Nitrates, and in Nitro Derivatives, by Kjeldahl's Process. M. L. Chenel. Bull. Soc. Chem. **7—8** (3), 321—327.

The author has obtained satisfactory results in the estimation of organic, ammoniacal, and nitric nitrogen by working Joldbauer's modification of the Kjeldahl process in the following manner:—0.5 grm. of the finely-divided substance is digested in the cold with a solution of 1.2 grms. phenol and 0.4 grm. phosphoric anhydride in 30 cc. of sulphuric acid, and agitated until solution is complete. Zinc powder (3 to 4 grms.) is then gradually added, and the mass kept cool until it is completely reduced, mercury (0.7 grm.) is then added, and the process continued as usual.

The following results were obtained in this way:—

	Total Nitrogen.		Maximum Error.	Mean Error.
	Calculated.	Found.		
Saltetre	13.86	$\left\{ \begin{array}{l} 13.91 \\ 13.82 \\ 13.73 \\ 13.96 \end{array} \right\}$	$\frac{1}{100}$	$\frac{1}{100}$
Ammonium nitrate .	35.00	$\left\{ \begin{array}{l} 35.31 \\ 34.90 \\ 34.96 \end{array} \right\}$	$\frac{1}{115}$	$\frac{1}{200}$
Barium nitrate.....	10.72	$\left\{ \begin{array}{l} 10.67 \\ 10.62 \end{array} \right\}$	$\frac{1}{100}$	$\frac{1}{100}$
Methylamine nitrate	29.79	$\left\{ \begin{array}{l} 29.65 \\ 29.68 \end{array} \right\}$	$\frac{1}{100}$	$\frac{1}{100}$
Nitroglycerol	18.50	18.45	..	$\frac{1}{100}$
Dinitrobenzene	16.67	$\left\{ \begin{array}{l} 16.78 \\ 16.57 \end{array} \right\}$	$\frac{1}{100}$	$\frac{1}{100}$
Paranitrophenol	10.07	10.03	..	$\frac{1}{100}$
Picric acid	18.34	$\left\{ \begin{array}{l} 18.42 \\ 12.17 \\ 18.43 \end{array} \right\}$	$\frac{1}{100}$	$\frac{1}{100}$
Ammonium picrate..	22.76	$\left\{ \begin{array}{l} 22.63 \\ 22.67 \end{array} \right\}$	$\frac{1}{100}$	$\frac{1}{100}$
Picramic acid.....	21.10	$\left\{ \begin{array}{l} 21.00 \\ 20.69 \end{array} \right\}$	$\frac{1}{100}$	$\frac{1}{100}$
Ammonium picramate	25.90	$\left\{ \begin{array}{l} 25.45 \\ 25.75 \end{array} \right\}$	$\frac{1}{100}$	$\frac{1}{100}$
Dinitro-ortho cresol..	14.14	$\left\{ \begin{array}{l} 14.10 \\ 13.98 \end{array} \right\}$	$\frac{1}{100}$	$\frac{1}{100}$
Trinitro-metacresol..	17.28	$\left\{ \begin{array}{l} 17.37 \\ 17.27 \end{array} \right\}$	$\frac{1}{100}$	$\frac{1}{100}$

The success of the operation appears to depend on the complete conversion of the phenol into the mononitro-derivatives; this takes place whenever the organic nitro-compound forms a clear solution in the cold sulphuric mixture. Substances like collodion or gun-cotton, however, be very finely divided for successful treatment.

The above method cannot be applied to tri- and tetra-nitrated naphthalenes, as these compounds do not dissolve completely in the cold sulphuric acid mixture. Kjeldahl's process may, however, be used if they are previously converted into the naphthylamines. This is readily effected as follows:—12 grms. of iodine are gradually added to a solution of 2 grms. of phosphorus in 15 or 20 cc. of carbon bisulphide contained in a 250 cc. flask, the whole is heated on the water-bath at 100° with constant turning until the last traces of the solvent are expelled; it is then cooled, the iodide of phosphorus detached from the sides of the flask by shaking, the weighed substance (0.5 or 0.6 grm.) introduced, water (8 grms.) added, and the flask turned round two or three times. When the reaction becomes brisk, the flask is shaken. In about a minute after the addition of the water, the reaction is finished; the flask is then cooled, 25 cc. of sulphuric acid (66°) and 0.7 grm. mercury gradually added, and the flask gently heated until the hydriodic acid is expelled. The operation

is continued as in the ordinary Kjeldahl process, except that the flask is heated a little more strongly towards the finish in order to volatilise the phosphonium iodide which condenses in the neck.

This method, which may be applied to the aromatic nitro-derivatives as well as to the nitro-naphthalenes, is especially useful for the analysis of impervious substances like collodion or gun-cotton, which dissolve so slowly in Joldbauer's mixture that loss of nitrogen cannot be avoided. The following results were obtained in this way:—

	Total Nitrogen.		Maximum Error.	Mean Error.
	Calculated.	Found.		
Dinitrobenzene	16.67	$\left\{ \begin{array}{l} 16.70 \\ 16.52 \end{array} \right\}$	$\frac{1}{100}$	$\frac{1}{100}$
Picric acid.....	18.34	$\left\{ \begin{array}{l} 18.23 \\ 18.18 \end{array} \right\}$	$\frac{1}{100}$	$\frac{1}{100}$
Ammonium picrate .	22.76	$\left\{ \begin{array}{l} 22.86 \\ 22.63 \end{array} \right\}$	$\frac{1}{100}$	$\frac{1}{100}$
Picramic acid.....	21.10	$\left\{ \begin{array}{l} 20.90 \\ 21.03 \end{array} \right\}$	$\frac{1}{100}$	$\frac{1}{100}$
Ammonium picramate	25.90	25.60	..	$\frac{1}{100}$
Dinitro-ortho cresol..	14.14	$\left\{ \begin{array}{l} 14.12 \\ 14.02 \end{array} \right\}$	$\frac{1}{100}$	$\frac{1}{100}$
Trinitro-metacresol .	17.28	$\left\{ \begin{array}{l} 17.05 \\ 17.26 \end{array} \right\}$	$\frac{1}{100}$	$\frac{1}{100}$

	Total Nitrogen.		Mean.	Maximum Error.	Mean Error.
	By Schloesing's Process.	By the modified Kjeldahl Process.			
Naphthalenes.

Sample F.	16.08	16.14
Sample G.	15.52	15.14

The figures given have been corrected for impurities in the reagents; this correction is obtained by making a blank experiment with each batch of reagents, and may be entirely neglected in the technical analysis of gun-cotton.

—S. B. A. A.

The Determination of the Purity of Olive Oils. F. Lengfeld and L. Paparelli. Rev. Internat. des Falsificat. **5**, 1892, 98.

The authors made a series of tests in order to compare the accuracy of different methods employed for detecting adulterations in olive oils. The oils designated A, B, C, D, E, F, I, K, P, Q, R were of Californian origin, and their purity was beyond dispute. The origin of the samples marked G, H, L, M, N, O was unknown. For comparison some samples of cotton-seed oil and of oil of white and black

mustard were likewise tested. It will be noticed that the iodine number of the pure olive oil samples was between 75.28 and 88.68. The rising of the temperature was

effected by means of a sulphuric acid of 66° B. Among the colour reactions, Bechli's test is especially characteristic for cotton-seed oil. The results are as follows:—

Designation of Oils.	Iodine Nos.	Rising of Temperature by Means of Sulphuric Acid.	Fatty Acids.	Melting Points of the Fatty Acids.	Bechli's Reagent.	Hancheborne's Reagent.	Brulle's Reagent.

—H. S.

The Determination of Fibrous Materials in a Crude State.
S. Gabriel. Zeits. f. physiol. Chem. **16**, 1892, 370.

This test is a modification of Höngig's method for the determination of crude fibres and starch (this Journal, 1890, 978), and is effected by dissolving caustic potash in glycerol and by heating this solution to 180° C. The details of the test are as follows: 33 grms. of caustic potash are dissolved in 1 litre of glycerol, and 60 cc. of this solution together with 2 grms. of the substance introduced into a flask of 250 cc. capacity, and heated on the wire gauze (not by means of a sulphuric acid bath, as Höngig proposes). The heating has to be carefully managed, as the mixture is inclined to boil over. After the temperature of 180° C. has been reached, the solution is allowed to cool down to 140° C., and then poured into a vessel containing 200 cc. of boiling water. After stirring, the mixture is allowed to stand, and, after some time, the liquid is drawn off from the precipitate which has been formed. The latter is once more treated with boiling water in the above-described manner, and then washed with 200 cc. of boiling water to which 5 cc. of hydrochloric acid of 25 per cent. strength have been added. Finally, the precipitate is washed with ether and alcohol. In many cases the very small amount of nitrogen contained in the substance may be disregarded.—H. S.

The Non-appearance of Multi-Rotation of Carbohydrates in Ammoniacal Solution. C. Schulze and B. Tollens. Annalen, **271**, 1892, 49—51. (Compare this Journal, 1891, 859.)

The authors, having found that when certain carbohydrates, which in aqueous solution exhibit multi-rotation, are dissolved in aqueous ammonia of sp. gr. 0.924, and immediately observed in the polarimeter, showed an optical activity even below the normal one, continued their experiments, using

	Aqueous Solutions.		Ammoniacal Solutions.	
	Time after Preparing Solution.	Specific Rotatory Power $[\alpha]_D$.	Time after Preparing Solution.	Specific Rotatory Power $[\alpha]_D$.
Dextrose (hydrate)	5 10 minutes (20 hours ..	90.69) 48.31)	8 minutes	48.309
Xylose.....	5 9 minutes (20 hours ..	67.14) 18.82)	5 "	18.88

Galactose.....	5 12 minutes (20 hours ..	127.93) 79.32)	8 "	78.46
Rhamnose.....	5 7 minutes (20 hours ..	6.17) 7.86)	7 "	7.95
Maltose (hydrate)	5 6 minutes (20 hours ..	95.83) 129.38)	7 "	129.42
Levulose.....	5 15 minutes (20 hours ..	— 32.30) — 30.89)	6 "	— 90.65
Semi-rotating milk sugar.....	5 7 minutes (20 hours ..	37.02) 54.93)	7 "	55.03
Ordinary milk sugar (hydrate).	5 30 minutes (20 hours ..	72.34) 52.01)	9 "	52.01

more dilute ammonia. Their results obtained in aqueous solution and in 0.1 per cent. ammoniacal solution are tabulated above. The solutions were mixed with cream of alumina, when necessary, and after making up to the mark filtered and polarised in a Schmidt and Haensch quartz compensating instrument, the calculations being made by

the formula $[\alpha]_D = \frac{0.246a.V}{p.l}$, in which α = the observed reading on the Ventzke scale, V the volume of the solution, p the weight of dissolved carbohydrate, and l the length of the observation tube. The solutions were all about 10 per cent.

Further experiments with dextrose proved that even with 0.01 per cent. ammonia, the specific rotatory power was $[\alpha]_D = 49.98$ 12–15 minutes after preparation, and $[\alpha]_D = 48.34$ 20 minutes after preparation. To observe abnormal rotatory power with carbohydrates which exhibit these phenomena, it is therefore necessary to employ water free from ammonia as solvent; whilst by the employment of 0.1 per cent. of ammonia as solvent, polarimetric work may be much shortened, inasmuch as the normal rotatory powers are obtained with the freshly-prepared solutions without heating them.—A. R. L.

Note on the Optical and Chemical Analysis of Butter.
F. Jean. *Monit. Scient.* 6, 1892, 91–98.

IN this paper the author replies at length to a number of objections raised against his method (this Journal, 1890, 218, 1072) of applying Amagat and Jean's "oleorefractometer" to the detection of adulteration in butter. Of these the only one of importance is, that perfectly pure butters may in some instances yield oleorefractometer deviations much below the normal (-30°), and would consequently be regarded as impure. Butters which exhibit this peculiarity have been found in all cases to be derived from the milk of cows fed on oil-cake; and there is no doubt that their abnormal behaviour must be ascribed to the presence of unaltered oil in the milk. The author admits that in such cases the oleorefractometer, if exclusively relied upon, will lead to erroneous conclusions; but claims that if employed conjointly with chemical tests it will yield complete information concerning all doubtful samples. The quantity of oil introduced into butter by the use of oil-cake as cattle food is too small to sensibly affect its "saponification equivalent" or the percentage of volatile acids; and it is shown that pure butter possessing an abnormal refracting power will yield a percentage of volatile acids somewhat above the accepted mean value ($27-28$ cc. $\frac{N}{10}$ alkali for 5 grms. of butter). On the other hand, in impure butters the volatile acids will be found below the mean value. The application of chemical tests, is, however, by no means necessary in every instance. Very many butters, especially of French origin, exhibit normal optical properties, and a number of samples may be rapidly sorted by means of the oleorefractometer into different classes, thus:—Deviation observed, $32^\circ-36^\circ$, purity of butters, doubtful; may contain palm or cocoa-nut oil; $31^\circ-29^\circ$, pure butters; $29^\circ-25^\circ$, purity doubtful. Volatile acids must be determined. Below 25° , impure butters. In the following table are given the analyses of a number of pure and adulterated butters. The letters above the columns represent:—A., oleorefractometer deviation; B., saponification equivalent in mgrms. of KOH per 1 gm. of butter; C., the number of cubic centimetres of $\frac{N}{10}$ alkali required to neutralise the volatile acids in 5 grms. of butter. (Determined by the Reichert-Meissl-Wollny process) (this Journal, 1887, 831); D., the percentage of fixed fatty acids; E., solubility of the butter-fat in glacial acetic acid (see this Journal, 1890, 113).

ANALYTICAL AND SCIENTIFIC NOTES.

Persulphuric Acid and its Salts. Berthelot. Bull. Soc. Chim. 7—8, 1892, 497—522.

MARSHALL'S researches (this Journal, 1891, 1004) have provided a method of preparing certain of the persulphates in tolerably large quantity, and have enabled the author to determine some of the more important thermo-chemical constants. The following are some of the results obtained:—

	Cal.
Heat of dissolution of potassium persulphate in 100 parts of water at 9.7° C. per gram. molecule	—14.36
Heat of dissolution of ammonium persulphate in 125 parts of water at 10.5° C. per gram. molecule	—9.72
Heat of dissolution of barium persulphate in 75 parts of water at 12° C. per gram. molecule.....	—11.38
Heat of neutralisation of persulphuric acid by barium hydrate	13.8
Heat of neutralisation of persulphuric acid by potassium or sodium hydrate.....	13.7
Heat of neutralisation of persulphuric acid by ammonia	12.4
Heat of decomposition of persulphuric acid according to the equation:	
$\text{H}_2\text{S}_2\text{O}_8$ (dilute) + $\text{H}_2\text{O} = 2\text{H}_2\text{SO}_4$ + O (free) ..	34.8
Heat of formation of persulphuric acid:	
S_2 (octahedral) + O_2 + H_2 + water = $\text{H}_2\text{S}_2\text{O}_8$ (dilute) ..	316.3
S_2 + O_2 + water = $\text{H}_2\text{S}_2\text{O}_8$ (dilute)	247.2

From these figures it appears that the decomposition of persulphuric acid involves an exothermic reaction. It occurs spontaneously in solution. The same remark applies to the salts. The potassium salt being anhydrous can only decompose with the formation of potassium pyrosulphate and oxygen, provided moisture be absent, and as this reaction gives rise to the evolution of only half the quantity of heat that is produced when an excess of water is present the dry salt is sensibly stable. The contrary tendency is exhibited by the barium salt as it contains four molecules of water of crystallisation, one of the products of decomposition being in consequence sulphuric acid, which acts on the remainder of the salt and forms a further quantity of sulphuric acid, so that the decomposition increases in geometrical progression. With regard to the mechanism of the formation of the persulphates, it may be said that as they are the products of an endothermic reaction they are necessarily formed by the intervention of external energy, which may result directly from the electric current employed or may be obtained from the effect of secondary reactions which are normal and exothermic. Hydrogen peroxide, for example, may be an agent of the kind. In dilute solution the reaction $2\text{H}_2\text{SO}_4 + \text{H}_2\text{O} = \text{H}_2\text{S}_2\text{O}_8 + 2\text{H}_2\text{O}$ is impossible because it involves the absorption 13.2 cal., but when the solution is concentrated its occurrence is no longer out of the question as the heat of hydration of sulphuric acid is 36.4 cal. for the two molecules required to effect the reaction indicated in the equation quoted above. Experiment confirms this surmise, as on treating barium peroxide with strong sulphuric acid in a vessel cooled with ice and pouring the product into water, a solution of persulphuric acid is obtained. If barium peroxide be added little by little, the mixture being kept cool, a point is reached at which the whole mass gives off vapours, the odour of which resembles that of ozone and hydrochlorous acid (possibly persulphuric anhydride?). If the residue be treated with water no persulphuric acid is found, and only a little hydrogen peroxide, the reaction resulting in the production of the former only taking place within certain limits of concentration.—B. B.

The Oxidation of Nickel Carbonyl. Berthelot. Bull. Soc. Chim. 7—8, 1892, 434.

NICKEL carbonyl can be preserved under water, but if contained in a bottle with an ordinary ground-in stopper becomes slowly oxidised, and a layer of apple-green nickel hydrate is formed, which the author has found to be free from carbon. A portion of it, however, makes its way out of the bottle and is oxidised, forming a fume which is deposited on adjacent objects. In order to examine the product of oxidation the author kept a bottle of nickel carbonyl in a double casing of tin-plate and succeeded in collecting a few decigrammes of a complex oxide, which appeared white in small quantity, but had a greenish tinge when viewed in mass. It was found to be the hydrated oxide of an organo-metallic compound of nickel, and upon analysis gave figures corresponding to the formula $\text{C}_2\text{O}_3\text{Ni}_3 \cdot 10\text{H}_2\text{O}$. It therefore appears to be the oxide of a complex radical analogous to croconic and rhodizonic acids.—B. B.

New Books.

TASCHENBUCH FÜR DIE SODA-, POTASCH-, UND AMMONIAK-FABRIKATION. Herausgegeben in Auftrage des Vereins Deutscher Sodafabrikanten und unter Mitwirkung der Commissions. Mitglieder J. Stroof, Dr. Jacobsen, Dr. E. Richters, Dr. L. C. Schwab and Dr. Siemann. Von Dr. G. LUNGE. Professor der techn. Chemie am eidgenöss. Polytechnikum in Zürich. Zweite, umgearbeitete Auflage. Berlin: Verlag von Julius Springer, 1892. London: H. Grevel and Co., 33, Covent Garden. 7s.

This is the 2nd German edition of the work known in this country as Lunge and Hurter's Pocket-Book for Alkali Makers. It is a small 8vo. volume, bound in leather, and sufficiently strong and limp to go easily into the pocket. The 14 engravings embellishing the text are beautifully executed. In this second edition the author expresses his indebtedness to the valuable contributions of Dr. Hurter which, reproduced from the English edition above referred to, appear here. Where any alteration in the methods and numerical values given in the 1st edition have been made Dr. Lunge states, that this has only been effected after a complete understanding with all the members of the German Verein deutscher Sodafabrikanten. The number of the alterations is, however, somewhat great, and still greater are the additions. A number of new tables, many estimations of new materials, and several new chapters (Zinc blende, Chlorate of Potash, Recovery of Sulphur (Chance), Beetroot molasses residue, Gas liquor, &c.). For the three acids and for ammonia, the new Tables constructed by Lunge and his students are given.

In these Tables the Baumé's hydrometer values in the first column are replaced by the actual specific gravities, and side by side are given the Baumé degrees, and also the Fleischer's Densimeter degrees, in the hope that ere long the latter will quite replace the Baumé degrees. These densimeter degrees are at once in close relationship with the actual specific gravities and with the English Twaddell degrees, since degrees Densimeter $\times 2 =$ degrees Twaddell, whilst on striking out the unit in specific gravity, the remainder $\times 100 =$ degrees Densimeter, or more concisely $n \text{ D} = 1 + 0.01n$.

Several improvements have also been made in the portion relating to Gasometrical estimations.

JAHRBERICHT UEBER DIE LEISTUNGEN DER CHEMISCHEN TECHNOLOGIE, MIT BESONDERER BERÜCKSICHTIGUNG DER GEWERBESTATISTIK, FÜR DAS JAHR. 1891. VON DR. FERDINAND FISCHER. Mit 193 Abbildungen. Leipzig: Verlag von Otto Wigand. 1892. London: H. Grevel and Co., 33 King Street, Covent Garden. 24s.

This work, already long known in this country through certain earlier translations, as "Wagner's Technology," has now for years past been conducted by Dr. Ferdinand Fischer of Göttingen. The present volume is the Annual Report or Jahresbericht for 1891, of the progress of Chemical Technology, and forms an 8vo. volume in paper cover, which contains Table of Contents, subject-matter extending over 1,187 pages, and Alphabetical Indexes of authors and subjects, and finally a Register of all the German patents referred to in the pages of the work, with the pages on which such references are made. The text is illustrated by 193 engravings referring to apparatus and plant, and the treatment of the whole subject is gathered from the following epitome of the sub-divisions of the same. GROUP I. CHEMICAL TECHNOLOGY OF FUEL (pages 1-123). Wood, Peat, Coal, and Coke. Petroleum. Ozokerite; Paraffin. Illuminating Gas. Illumination. Water- and Generator-Gases. Furnaces and Furnace Arrangements, &c. Heating and Ventilation. Processes of Investigation. Calorimetry. Photometry. Statistics. GROUP II. CHEMICAL METALLURGY (pages 124-312). Iron, Slags, their formation and utilisation. Preparation of Pig iron. Casting Iron. Purification of Iron; Steel. Manganese, Cobalt, Nickel, Chromium. Aluminium. Sodium and Potassium. Copper, Lead, and Silver. Gold. Zinc and Cadmium. Other Metals. Alloys and Metal plating. New Books. Statistics. GROUP III. CHEMICAL MANUFACTURES: INORGANIC (pages 313-577). Sulphur and Bisulphide of Carbon. Sulphuric Acid. Ammonia. Salt and the Salt Industry. Potash Salts. Soda. Hydrochloric Acid and Chlorine. Bromine and Iodine. Nitric Acid, Nitrates, and Nitrites. Phosphorus, Phosphoric acid. Phosphates. Explosives. Magnesium, Strontium, and Barium Compounds. Aluminium Compounds. Chromium and Lead Compounds. Antimony and Arsenic Compounds. Other Compounds. Oxygen and Hydrogen. Water and Ice. New Books. Statistics. GROUP IV. CHEMICAL MANUFACTURES: ORGANIC (pages 578-754). Alcohol preparations. Organic Acids. Aromatic Compounds. Organic Colouring Matters. Naphthalene and Anthracene Colours. Azo Colours. Other Organic Colouring Matters. Alkaloids. Etheral Oils. Other Organic Compounds. New Books. GROUP V. GLASS, EARTHENWARE, CEMENTS, ARTIFICIAL STONE, &c. (pages 755-810). GROUP VI. FOODSTUFFS (pages 811-1108). Flour and Bread. Starch and Dextrin. Sugar. Statistics. FERMENTATION INDUSTRIES. A. Fermentation and Yeast. B. Wines. C. Beers. D. Spirits. Milk, Butter, and Cheese. Meats. Coffee, Tea, and Cocoa, &c. Fodders. New Books. Statistics. GROUP VII. CHEMICAL TECHNOLOGY OF FIBRES (pages 1109-1160). Fibrous Materials. Bleaching. Dyeing and Printing. Paper. New Books. GROUP VIII. OTHER ORGANIC CHEMICAL INDUSTRIES (pages 1161-1187). Fats, Oils, and Lubricants. Fatty Acids, Soaps, Glycerin. Varnishes, Resins, Paints. India Rubber, &c. Tanning, Glues. Manures, &c. Preserving Wood.

COMMERCIAL ORGANIC ANALYSIS. A Treatise on the Properties, Analysis, &c. of Organic Chemicals and Products used in the Arts, Manufactures, Medicine, &c. with concise Methods for the Detection and Determination of their Impurities, Adulteration, and Products of Decomposition. By ALFRED H. ALLEN, F.I.C., F.C.S. Second Edition, Revised and Enlarged. Vol. III. Part II. Amines and Ammonium Bases, Hydrazines, Bases from Tar, Vegetable Alkaloids. 1892. London: J. and A. Churchill, 11, New Burlington Street. 18s.

This work having grown through the recent extraordinary development of the subjects treated of, the author has been compelled to divide his Vol. III. into three parts, each of which fills a good sized volume. The present book is Part II. of Vol. III., and it takes the form of an

8vo. volume, bound in cloth, and containing Preface, Table of Contents, and subject-matter filling 572 pages. Two beautifully executed plates illustrate the appearances of photographs of various leaves of the tea and coffee plants and also of others which are sometimes used to adulterate teas and coffees. The book is completed by an Alphabetical Index of subjects and a list of Errata.

The subjects treated of are as follows:—AMINES and AMMONIUM BASES. Monamines. Ammonium Bases. HYDRAZINES. Hydrazine. Substituted Hydrazines. BASES FROM TAR. Classification of Tar Bases. Aniline and its Allies. Naphthylamines and their Allies. Pyridine Bases. Quinoline, Acridine. VEGETABLE ALKALOIDS. Character and Classification of Alkaloids. General Reactions. Isolation and Purification. Constitution and Synthesis. Volatile Bases of Vegetable Origin. Aconite Bases. Atrophine. Tropeines. Coca Alkaloids. Opium Alkaloids. Strychnos Alkaloids. Cinchona Alkaloids. Berberine, &c. Caffeine.

Under the head of the various poisonous as well as medicinal bases, &c. not only is the chemistry of these bodies treated of, but the best methods of preparation, analytical reactions, toxicology and descriptions of medicinal preparations, are given in considerable detail. The classified and systematically treated articles on Tobacco and Opium are of much interest, and the subject of Morphimetry alone covers upward of 10 pages, if we include also the extract of opium and its assay. With regard to the cultivation and use of opium in smoking and eating in the East, &c., the author quotes Dr. W. Moore of Bombay, who compares excess in opium to that in the use of "spirits, of roast goose, or even of fruit." The subject of the Cinchona Barks, their assay, and the separation of the Bases, &c. covers some 21 pages. The treatment of Tea, Coffee, and Cocoa occupies no less than 73 pages, which are illustrated by many tables, analytical and otherwise.

EXPLOSIVES AND THEIR POWER. Translated and Condensed from the French of M. Berthelot by C. NAPIER HAKE and WM. MACNAB. With a Preface by Lieut.-Col. J. P. CUNDILL, R.A. With Illustrations. London: John Murray, Albemarle Street. 1892. 24s.

LARGE 8vo. volume, bound in cloth, containing Preface, Table of Contents, Subject-matter containing 553 pages, and Alphabetical Index. The subject-matter includes, from page 543-553, an Appendix on detonating gaseous mixtures, on the rapidity of propagation of detonation in solid and liquid explosives, and on the different modes of explosive decomposition of picric acid and nitro-compounds. The work is illustrated with between 40 and 50 wood cuts, and is classified into three books, viz., Book I. General Principles. Book II. Thermo-Chemistry of Explosive Compounds; and Book III. Force of Explosive Substances in Particular. These comprise the following courses of subdivision:— I., Chap. i. The force and work done by explosive substances. ii. Products of explosive decomposition, &c. iii. Heat and energy disengaged. iv. Pressure of gases, temperature, &c. v. Duration of explosive reactions, &c. vi. Explosion by influence, &c. vii. Explosive wave. II. Chap. i. General principles of thermo-chemistry of Explosives. ii. Calorimetry. iii. Heat of formation of oxygenated compounds of nitrogen, &c. iv. Heat of formation of the nitrates. v. Origin of the nitrates. vi. Heat of formation of hydrogenated nitrogen compounds. vii. Ditto of nitrogen sulphide. viii. Ditto of compounds of nitric acid with organic substances, &c. ix. Diazo-compounds. x. Heat of formation of mercury fulminate. xi. Ditto of cyanogen series. xii. Oxygenated compounds of chlorine, bromine, and iodine. Thermal formation of chlorates. Combustion effected by potassium chlorate disengages more heat than by free oxygen, &c. xiii. Metallic oxalates. Conditions under which they are explosive. III. Chap. i. Classification of explosives. Definition, &c. ii. General data respecting employment of given explosive. iii. Explosive gases and detonating gaseous mixtures. Their maximum work, &c. iv. Definite non-carburetted explosive compounds. v. Nitric ethers, &c. vi. Dynamites, &c. vii. Gun-cotton

and nitro celluloses, &c. viii. Pieric acid and pierates, &c. ix. Diazo-compounds. x. Powders with a nitrate base, &c. xi. Powders with a chlorate base. Dangers of chlorate powders, &c. xii. Conclusions. Summary.

JAHRBUCH DER CHEMIE. Bericht über die wichtigsten Fortschritte der reinen und angewandten Chemie, unter Mitwirkung von H. Beckurts, R. Benedikt, C. A. Bischoff, E. F. Duire, J. M. Eder, E. Valenta, C. Häussermann, G. Krüss, M. Mareker, L. Bähring, W. Nernst, F. Röhmman. Herausgegeben von RICHARD MEYER. Erster Jahrgang, 1891. Frankfurt a/M. Verlag von H. Bechhold. London: H. Grevel and Co., 33 King Street, Covent Garden. Bound in cloth, 12s. Elegantly bound, 13s. 6d.

This new Chemical Jahresbericht gives a resumé of the advance of Chemistry and Chemical Technology during the year 1891, and thus a kind of retrospect is afforded of the advance, both of pure chemistry and its principle applications. The work commences with a preface by Professor R. Meyer, a list of his collaborators, and a Table of Contents. The subject-matter covers 518 pages and the work concludes with Alphabetical Indexes of subject-matter and authors. The sub-division of the work indicates the mode of treatment of the whole subject and is as follows:—I. Physical Chemistry. II. Inorganic Chemistry. III. Organic Chemistry. IV. Physiological Chemistry. V. Pharmaceutical Chemistry. VI. The Chemistry of Foods, &c. VII. Agricultural Chemistry. VIII. Metallurgy. IX. The Technology of Inorganic Chemistry. X. Explosives. XI. Technology of the Carbohydrates and of Fermentation. XII. Technology of Fats. XIII. The Chemistry of Coal Tar and Coal Tar Colours. XIV. Photography.

The book is handsomely bound in cloth, and is of 8vo. size.

Trade Report.

TARIFF CHANGES AND CUSTOMS REGULATIONS.

FRANCE.

Customs Decisions.

The following decisions affecting the classification of articles in the French Customs tariff have recently been given by the French Customs authorities:—

"Carbonated crystal."—Category 247. Duty 4 francs 10 cents, per 100 kilos.

Tin precipitate, in fine powder, for the manufacture of "silver" papers, is dutiable as colours not distinguished.

Japanese varnish, consisting of acetate of amyl, methylic alcohol, benzine, and pyroxyline or gun-cotton; liquid preparation consisting of acetate of amyl, methylic alcohol, and benzine, used for diluting the above-named varnish.—Category 298, 2nd paragraph, duty, 30 francs per 100 kilos.

Oil-paper for tracing plans and drawings, and used for the same purposes as sulphurised paper.—Category 461 *ter*, duty 20 frs. per 100 kilos.

ITALY.

Classification of Articles in Customs Tariff.

Note.—Quintal = 220·4 lb. avoirdupois. Lire = $9\frac{16}{100}$ d.

The following decisions affecting the classification of articles in the Italian Customs tariff have recently been given by the Italian Custom authorities:—

Glass bottles with stoppers for druggists' use.—Category 258b. Duty 15 lire per quintal.

Glass phials, polished with emery.—Category 258b. Duty, 15 lire per quintal.

Demijohns of sheet iron, tinned, containing glycerin. The recipients are charged separately from the goods which they contain.

Sheets of metallic alloys not distinguished. Assimilated to metallic alloys in the raw state.—Category 221a.

Powder of jalap.—Category 62. Duty, 120 lire per quintal.

Sulphate of barytes made up with water.—Category 43b. Duty, 1 lire per quintal.

Extract of quebracho.—Category 30c. Exempt from duty.

UNITED STATES.

A case involving the basis of the duty on certain copper ores was heard by the General Appraisers in New York October 27th. The special point involved was the duty on Rio Tinto pyrites imported by certain sulphuric acid manufacturers. Expert testimony was taken, and the Secretary of the Treasury will decide upon the question. The present duty on copper ores is one-half cent. per pound of fine copper contained. The importation of copper ore reckoning on the basis of fine copper contained, for the seven months ending July 31st, 1891, was 6,270,003 lb., and for the same period in 1892, 3,819,446 lb.—*Eng. and Mining Journal*.

GENERAL TRADE NOTES.

THE JAPANESE CAMPHOR TRADE.

The following particulars respecting the Japanese camphor trade are extracted from a recent report by the United States Consul at Osaka:—

The camphor tree, from which the resinous gum is distilled, is a species of the laurel, and is found in the provinces of Tosa, Hiuga, and Satsuma, in the south of Japan. Large groves of the trees are owned by the Japanese Government, the wood being very desirable for shipbuilding. The districts in which the camphor tree is found are mountainous and situated far from the sea. No reliable information can be obtained as to the cost of producing the gum before being transported in junks to Hiogo. The peasants who engage in distilling the roots and branches of the trees are said to be poor, and employ the rudest machinery.

The market value of crude camphor gum and of oil of camphor per picul (133½ lb.) during the past year was as follows:—Drained, 38·25 dols.; wet, 37·00 dols.; old dry, 43·50 dols.; average, 36·50 dols.; camphor oil, 5·25 dols.

The highest and lowest prices during the same period were as follows:—Highest, 40·00 dols.; lowest, 33·00 dols.

Camphor gum is exported in tubs measuring about 6½ cubic feet; oil in kerosene tins and cases. The grades are from old dry down to new wet, and the various grades depend upon the quantity of adulteration. In oil there are two grades—white and brown.

Adulteration is practiced for the most part by adding water and oil just as far as the buyer will tolerate. In some cases 20 lb. of water will run out of a tub in 12 hours. The unadulterated article, known as the good old dry, can sometimes be bought. The only system of tests in determining value of the different qualities is by burning and by absolute spirit. The percentage of pure camphor which the crude yields when refined varies accordingly to the quality of the crude. The average percentage of gum produced from the wood as compared with the original weight of the wood cannot be accurately ascertained here, the only foreigner known to have visited the camphor districts having declined to furnish any information on the subject.

The total exports of camphor from Hiogo during 1891 in cattiees of 1½ lb. each amounted to 3,850,400 cattiees consigned to the following destinations; Europe (countries not specified), 1,777,300 cattiees; London, 335,600 cattiees; Germany, 209,200 cattiees; United States, 1,277,000 cattiees; China, 51,900 cattiees; France, 199,400 cattiees.

As regards the manufacture of camphor, the following particulars are extracted from a report by the United States Consul at Nagasaki.

Camphor is found alike on high elevations and in the valleys and lowlands. It is a hardy vigorous, long-lived tree, and flourishes in all situations.

Many of these trees attain an enormous size. There are a number in the vicinity of Nagasaki which measure 10 and 12 feet in diameter. The ancient temple of Osuwa, at Nagasaki, is situated in a magnificent grove of many hundred grand old campher trees, which are of great age and size, and are still beautiful and vigorous. It is stated that there are trees at other places in Kin Shin measuring as much as 20 ft. in diameter. The body or trunk of the tree usually runs up 20 and 30 ft. without limbs, then branching out in all directions, forming a well-proportioned, beautiful tree, ever green and very ornamental.

The leaf is small, elliptical in shape, slightly serrated, and of a vivid dark-green colour all the year round, except for a week or two in the early spring, when the young leaves are of a delicate tender green. The seeds or berries grow in clusters and resemble black currants in size and appearance. The wood is used for many purposes, its fine grain rendering it especially valuable for cabinet-work, while it is used also for shipbuilding. The roots make excellent knees for ships.

In the manufacture of camphor the tree is necessarily destroyed, but by a stringent law of the land, another is planted in its stead. The simple method of manufacture employed by the natives is as follows:—

The tree is felled to the earth and cut into small pieces, or more properly speaking, into chips.

A large metal pot is partially filled with water and placed over a slow fire. A wooden tub is fitted to the top of the pot, and the chips of camphor wood are placed in this. The bottom of the tub is perforated so as to permit the steam to pass up among the chips.

A steam-tight cover is fitted on the tub. From this tub a bamboo pipe leads to another tub, through which the enclosed steam, the generated camphor and oil flow. This second tub is connected in like manner with a third. The third tub is divided into two compartments, one above the other, the dividing floor being perforated with small holes, to allow the water and oil to pass to the lower compartment. The upper compartment is supplied with a layer of straw, which catches and holds the camphor in crystal in deposit as it passes to the cooling process. The camphor is then separated from the straw, packed in wooden tubs of 133½ lb. each, and is ready for market.

After each boiling the water runs off through a faucet, leaving the oil, which is used by the natives for illuminating and other purposes.—*Board of Trade Journal*.

A NEW OIL SEED.

The *Kew Gardens Bulletin* for October publishes the following notice:—

Amongst the numerous oil seeds that are constantly being received at Kew, for the purpose of naming, from Liverpool brokers and seed crushers, were some that made their first appearance at Liverpool from the West Coast of Africa in February 1891. They appear to have attracted a considerable amount of attention, judging from the fact that they were received at Kew from several different brokers about the same time, and a month later, in March 1891, samples were also received from Germany. Quite recently the same seeds have again appeared, having been sent to Kew by a seed-crushing firm at East Greenwich. The interest attached to them from a commercial point of view is probably due to the quantity of oil their kernels seem to contain, rather than to its quality or properties, for up to the present these appear not to have been tested; they may, however, become an important source both of oil and oil-cake, for though nothing definitely is known as to the plant producing them, inasmuch as no other material than the fruits themselves, without the fleshy coverings, have been received at Kew, it is clear from these alone that the plant belongs to the natural order *Oleaceæ*, and probably to the genus *Heisteria*. The fruits as received are hard and woody, requiring some force to break them; they are ovate in form, above 1 in. long and $\frac{3}{4}$ in. in diameter, of a dull earthy brown colour, marked by irregular longitudinal striations, the inside being filled with a whitish, fleshy, and very oleaginous kernel. From the fact that the plants constituting this order are free from any poisonous or deleterious properties, and that the fruits of some of the species are edible, it may be inferred that this new oil seed may prove of some commercial value. No locality has been given whence the seeds have been obtained, the only information on that head being, as before stated, that they were imported from the West Coast of Africa.

A NEW VARIETY OF SUGAR CANE.

The *Kew Gardens Bulletin*, referring to a new variety of sugar cane which is stated to have been discovered in the Upper Niger region of Central Africa, says:—

"It is described as a giant variety possessing great saccharine richness, and capable of being readily reproduced from seed which in this variety is well developed. Several inquiries have already been addressed to Kew in regard to this cane, and it may be well to state at once that there are grounds for believing that the plant mentioned is not a sugar-cane at all, but the ordinary guinea corn or sorghum (*Sorghum vulgare*), which is widely distributed over Africa. This plant, it is well known, yields a useful syrup, and strenuous efforts are being made in the United States at the present time to extract a granulated sugar from it. Should the Niger plant prove to possess any special merits as a sorghum we shall, no doubt, hear more about it. It can have, however, little or no interest to the tropical sugar-planter."

PETROLEUM IN UPPER BURMA.

Dr. Fritz Noetling, Geological Survey of India, has written a very interesting account of the petroleum industry in Upper Burma. Dr. Noetling estimates that there are now 602 wells, an increase of 92 since 1888. These produce about 17,700 viss (viss is equivalent to $3\frac{1}{2}$ lb. avoirdupois) per day, but there are, in Dr. Noetling's opinion, distinct signs of exhaustion. The fact that the aggregate production of the richer wells has fallen off, while that of the poorer ones has increased, although many new wells have been opened, is regarded as the surest indication of the approaching decline in the industry. The drilled wells worked by the Burma Oil Company and the Burma Oil Syndicate have given very satisfactory results. In 1890 the total out-turn amounted to over 3,670,000 viss; but the rate of progress during 1888, 1889, and 1890 has not been maintained during the past two years. The history of the industry shows that the production of the oil-field steadily increased from the beginning of the century till about 1873,

when it began to decline, rising again in 1885, and coming practically to a standstill in 1891. — *Board of Trade Journal*.

SOAP LAKE, WASHINGTON.

Professor J. C. Russell, of the United States Geological Survey, gives the following information concerning the water of Soap Lake in Douglas county, and compares it with that of other alkaline waters. The sample analysed contained sediment amounting to four parts in 1,000,000. He says: "The absence of calcium carbonate is of interest, since deposits of that salt are now taking place on the lake bottom through the agency of low forms of plant life. Compared with other alkali lakes of the West, Soap Lake contains but a small quantity of the alkaline metals, as the following analyses show:—

Constituents in Parts Per thousand.	Great Salt Lake, Utah, 1869.	Soda Lake, near Rye-town, Nev.	Mono Lake, California.	Owen's Lake, California.	Soap Lake, Washington.

THE IODINE CONVENTION.

We hear from an official and neutral source in Iquique (Chili) that, although the Iodine Convention is still in force at this moment the agreement will not remain tenable for long (the report was penned about two months ago), because under the operation of the Convention the stock of iodine is accumulating to such an extent that there will soon be enough for three years' consumption. It is, therefore, sought to arrive at an understanding upon a new basis, upon which it is proposed either to stop the production altogether for a period, or at any rate to limit it to such an extent that the accumulated stocks will have a chance of absorption by the ordinary consumption. The exports of iodine from Iquique in 1891 were 9,144 quintals, of which 1,823 went to Liverpool, 5,147 to Hamburg, 1,764 to New York, and 399 to other ports. The producers who do not belong to the Union exported 74 quintals. The nitrate combination, which was formed in 1891, will, so far as the present arrangements go, remain in force until the end of 1892. There is hardly any doubt that it will be renewed.—*Chemist and Druggist*.

ARTICLES OF INTEREST TO TECHNOLOGISTS AND MANUFACTURERS.

The following articles, which appear in the *Board of Trade Journal* for November, will repay perusal.

"Foreign Competition with Great Britain in trade with Uruguay"	p. 536
"Trade Requirements in Guatemala."	p. 540
"New Customs Tariff of Porto Rico"	p. 553

Monthly Patent List.

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—GENERAL PLANT, APPARATUS, AND
MACHINERY.

APPLICATIONS.

18,793. F. J. R. Carnila. Improvements in apparatus for concentrating and evaporating liquids. October 20.

18,879. T. Thorpe and T. G. Marsh. Improvements in or connected with gas condensers. October 21.

18,891. T. G. Webb. See Class VIII.

18,941. W. A. Swain. See Class XVII.

19,147. H. H. Lake. —From O. B. Stillman, United States. Improvements in evaporating apparatus. Complete Specification. October 25.

19,149. H. W. Rappleye. Improvements in drying apparatus. Complete Specification. October 25.

19,213. I. Levenstein. See Class VII.

19,558. A. Lappin. Improvements in distilling apparatus. October 31.

19,611. A. Gray and J. W. Newall. Improvements in the production of steam. November 1.

19,653. P. M. F. Laurent. A method and apparatus for use in the manufacture of ice. November 1.

19,755. A. G. Glasgow. Improvements relating to pressure gauges. November 2.

19,789. A. Boake and F. G. A. Roberts. Improvements in vessels for containing sulphur dioxide. November 3.

19,837. A. H. Wendt. Improvements in apparatus for controlling the flow of acid or other liquid to and from casks or other receptacles. November 3.

20,299. W. W. Pope. Improvements relating to vessels for containing gas under pressure. November 10.

COMPLETE SPECIFICATIONS ACCEPTED.*

1891.

17,886. H. H. Lake. —From La Société Anonyme du Compresseur Jourdan, France. Apparatus for expressing liquids from vegetable, animal, or mineral substances. October 26.

19,486. D. B. Morison. Improvements in apparatus for heating or evaporating liquids. October 26.

19,780. C. J. Schofield. See Class VII.

20,125. G. Y. Blair. Apparatus for evaporating, condensing, and the like. October 26.

20,904. C. H. Fitzmaurice. Apparatus and appliances for softening, purifying, and filtering liquids. November 16.

21,507. J. Brotherton. Bottles or holders for the storage and conveyance of quicksilver, gas, and other fluids under high pressure, and method of manufacture thereof. November 2.

22,248. J. Pullman and H. S. Elworthy. See Class XVII.

22,607. D. Rylands. Furnaces, retort chambers, and the like. November 2.

22,655. H. Williams. See Class VII.

22,656. H. Williams. Method and apparatus for drying malt, hops, grain, pulse, and other substances. November 2.

22,870. J. Pullman and H. Lane. Construction of compressing machinery or apparatus for the condensation and liquefaction of gases. November 16.

1892.

138. E. Brook. Furnaces. November 9.

765. S. Fox. Furnaces for the application of water-gas for heating and welding purposes. November 16.

15,122. W. H. Beek. —From B. de Lissa, Australia. See Class II.

15,698. F. W. Golby. —From B. Jardin. Apparatus for heating air. October 26.

16,308. W. Maybach. Apparatus for effecting a continuous circulation and cooling of cooling liquids employed in motors and compressors. October 26.

16,403. C. W. Cooper. Apparatus for evaporating liquids. November 16.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

18,581. D. Terrace. An improved apparatus or appliance for heating inclined gas retorts. October 17.

18,605. G. Hüttemann and G. Spieker. Improvements in the manufacture of blocks or briquettes of fuel from small coal, slack, coal-dust, and coke-dust. October 18.

18,615. W. Fiddes. Improvements in the method and apparatus for charging gas retorts. October 18.

18,680. J. Yonge. An improvement in night lights, candles, and similar means of illumination. October 19.

18,904. J. Hodges. See Class III.

18,990. L. H. Armonr. Improvements in the manufacture of illuminating gas. October 22.

19,078. L. Chapman. Improvements in and apparatus for the production of oxygen and nitrogen from atmospheric air. October 24.

19,477. R. Caupion. The employment of certain ingredients and means for the manufacture of fire-lighters therefrom. Complete Specification. October 29.

19,483. A. W. Wells.—From F. Verrue, Belgium. A new or improved apparatus for carburetting gas and air for illuminating and heating purposes. Complete Specification. October 29.

19,630. H. Galopin. Improvements in and connected with apparatus for using liquid fuel for lighting and heating purposes. Complete Specification. November 1.

19,655. H. G. O'Neill. Improvements in and relating to a method of and means for heating by electricity. Complete Specification. November 1.

19,753. A. G. Glasgow. Improvements relating to apparatus for the manufacture of water-gas. November 2.

19,997. J. Goetz. Improved apparatus for separating tar and ammonia from gas. November 7.

20,341. P. A. Fichet and R. Heurtey. Improvements in the production and the use of gaseous fuels. November 10.

20,373. W. G. Hay. Improvements in and connected with the manufacture of fire-lighters. November 11.

20,429. A. J. Eli.—From M. A. Braconnier, France. A new or improved process for utilising the waste heat of zinc works. November 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

20,573. J. Hargreaves. Feeding fuel to gas producers and generation of combustible gas. November 2.

21,563. W. Bagley. Apparatus for feeding coal to gas producers. November 16.

22,106. C. E. Bell. Improvements in coke ovens to facilitate the cooling of the coke before drawing. October 26.

22,292. J. A. Yeadon and W. Adgie. Heating retorts or furnaces for the distillation of coal or other analogous purposes. November 16.

22,340. J. Pullman and H. S. Elworthy. Process for the manufacture of carbonic acid gas and hydrogen gas, and for the separation of the two gases, and apparatus therefor. October 26.

1892.

24. H. Williams. Gas purifying apparatus. November 9.

15,122. W. H. Beck.—From B. de Lissa. Apparatus for making and storing a mixture of inflammable gas and air. November 16.

17,262. R. M. Bidelman. Manufacture of gas. November 2.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

APPLICATION.

18,904. J. Hodges. Improvements in the treatment of paraffin scale and other crude paraffins. October 21.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

18,721. R. J. Friswell and F. H. Leeds. Improvements in the manufacture of copyable inks. October 19.

18,762. H. S. Elworthy. An improved method of and apparatus for oxidising indigo liquor. October 19.

19,246. H. E. Newton. — From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of new colouring matters. October 26.

19,411. R. W. E. Melvor and A. Cruickshank. A process for the production of blue ultramarine from the material known as green ultramarine. Complete Specification. October 28.

19,557. H. E. Newton. — From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of new colouring matters. October 31.

19,743. H. E. Newton. — From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of new azo-colouring matters. November 2.

19,820. O. Imray. — From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. A new manufacture of red colouring matter. November 3.

19,826. J. Sniechowski. Improvements in the production of black and brown colours. November 3.

19,891. Brooke, Simpson, and Spiller, Limited, and A. G. Green. Improvements in the manufacture of azo-colouring matters. November 4.

20,423. J. Rohner. Manufacture of new colouring matters of the series of the indulines by the action of the diamido-di-alkylthioureas on the aromatic amines. Complete Specification. Filed November 11. Date applied for April 14, 1892, being date of application in France.

20,506. B. Willecox. — From The Badische Anilin und Soda Fabrik, Germany. Improvements in the manufacture and production of dyestuffs, suitable for dyeing vegetable fibre with or without a mordant. November 12.

20,512. G. M. Keevil. A new or improved manufacture of ink. November 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

22,641. B. Willecox.—From The Farbenfabriken vormals F. Bayer and Co. Manufacture of new colouring matters. November 2.

22,641A. B. Willecox.—From The Farbenfabriken vormals F. Bayer and Co. Production of azo colours on fibre. October 26.

1892.

277. C. D. Abel.—From The Actien Gesellschaft für Anilin Fabrikation. Manufacture of new colouring matters. November 9.

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATIONS.

18,572. P. Jensen.—From E. Stierner and M. Ziegler, Germany. Process of and apparatus for working up organic fibrines for producing sheets, roofing and wall felts, matches, torches, and the like. Complete Specification. October 17.

19,737. H. W. Godfrey, C. F. Leake, and C. E. Lucas. Improvements in the manufacture of floor-cloth. November 2.

19,770. E. Ostlere and W. F. Denholm. Improvements in the manufacture of tessellated or inlaid floor-cloth. November 3.

19,776. F. Doller and R. Wolfenstein. Process and apparatus for waterproofing woven fabrics. Complete Specification. November 3.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

18,470. C. G. Hagemann. Manufacture or production of cellular substance and textile fibre. October 26.

19,135. L. E. Vial. Treatment of China-grass, and other plants adapted for employment in the textile industry. November 16.

1892.

477. G. Hagemann. See Class XIX.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

18,843. J. E. L. Roche. An improved process of dyeing, dressing, and waterproofing fabrics. Filed October 20. Date applied for March 21, 1892, being date of application in France.

18,975. D. Jackson. Improvements in the method of and apparatus for hank dyeing. October 22.

19,079. F. Schreurs. A new process and apparatus for printing and dyeing fabrics. Complete Specification. October 24.

19,359. L. Ettl. A new or improved process and apparatus for dyeing, bleaching, and boiling. Complete Specification. October 28.

19,796. J. Rhodes, sen., and J. Rhodes, jun. Improvements in machinery for dyeing, washing, or treating with liquids, hanks or skeins of yarn, slubbing or other fibrous material. November 3.

20,444. P. A. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in the production of fast colours on fibres by means of dyeing and printing. November 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

20,103. P. G. Wild, G. Bentley, J. B. Jackson, and A. A. Whitley. Method of stamping and tinting textile fabrics and apparatus for effecting same. October 26.

22,538. E. Zillessen, sen. Dyeing silk or half silk goods. October 26.

22,641A. B. Willcox.—From The Farbenfabriken vormals F. Bayer and Co. See Class IV.

1892.

148. A. Dreze. Dyeing vats. November 9.

4278. H. Thies and E. Herzig. Bleaching. November 9.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

18,598. F. P. Candy. Improvements in and in connection with the manufacture of iron sulphate, and of materials for use in the filtration and precipitation of sewage and polluted waters. October 18.

18,810. H. Steinem. Improvements in the manufacture of carbonic acid gas. October 20.

18,871. J. Hargreaves and T. Bird. Improvements in the manufacture of alkali and in apparatus therefor. October 21.

18,900. C. H. W. Hæpfner. Improvements in the manufacture of cuprous oxide. October 21.

18,917. O. J. Steinhart. Improvements in the production of cyanides of the alkali and alkali-earth metals. October 21.

19,143. J. S. MacArthur, R. W. Forrest, and W. Forrest. Improvements in obtaining cyanogen compounds. October 25.

19,180. J. M. Milnes and A. Milnes. A new process or means for the production of chloride of lime. Complete Specification. October 25.

19,213. I. Levinstein. Improvements in the method of and apparatus for concentrating sulphuric acid and other liquids. Complete Specification. October 26.

19,447. R. Ashton. Improvements in the preparation of compounds for making vinegar. October 29.

19,812. L. Mond. Improvements in obtaining ammonia, chlorine, and hydrochloric acid from ammonium chloride. November 3.

20,055. W. J. Fraser and L. McGregor Fraser. Improvements in the manufacture of bleaching powder and like compounds, and in apparatus therefor. November 7.

20,070. W. T. Thorp. Manufacture of improved substances from salt. November 8.

20,202. T. Hyatt and T. Rickett. Improvements in the preparation of acids and alkalis, and in baking powders and self-raising flour prepared therewith. November 9.

20,269. M. P. Hatschek. Improvements in the manufacture of sulphurous acid and its compounds, sulphites and bi-sulphites of lime, soda, and the like. November 10.

20,284. P. de Wilde, A. Reyckler, and F. Hurter. Improvements in apparatus for the manufacture of chlorine. November 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

18,482. J. E. Bott. Manufacture of caustic alkalis. October 26.

19,780. C. J. Schofield. Apparatus for concentrating sulphuric and other acids. November 16.

22,340. J. Pullman and H. S. Elworthy. See Class II.

22,655. H. Williams. Method and means for recovering salts from brine and solutions, and for concentrating solutions.

22,828. J. J. Meldrum and T. F. Meldrum. Supplying liquor to ammonia stills. November 9.

1892.

2604. J. Morris. Process for the production of crystals and crystalline masses. November 16.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

APPLICATIONS.

18,891. T. G. Webb. Improvements in the manufacture of open glass retorts or vessels used in the concentration of sulphuric acid, and in apparatus therefor. October 21.

19,361. A. S. Ford. See Class X.

19,395. P. A. Moreau. Improvements in the production of ornamental stones artificially coloured. Complete Specification. October 28.

19,970. J. A. Yeadon and W. Adgie. Improvements in the manufacture of fire-bricks, retorts, crucibles, and other analogous articles. November 5.

20,441. S. D. Pochin and H. D. Pochin. Improvements in the manufacture of tiles. November 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1892.

46. R. F. Yorke. Earthenware pipes. November 16.

117. D. Rylands. Jars and similar receptacles for sterilised milk and similar preparations. November 9.

16,792. F. Shuman. Apparatus for manufacturing sheet glass having wire or wire netting embedded within it. November 9.

17,848. P. Sievert. Process for producing flat objects of glass, and means for carrying out such process. November 16.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

18,575. H. J. Haddan.—From F. D. Cummer, United States. Improvements in the process of drying and disintegrating clay and similar materials. Complete Specification. October 17.

18,803. K. Alsdorff. Improvements in fireproof walls and ceilings. Complete Specification. October 20.

19,009. J. Thomlinson. Improvements in the manufacture of non-efflorescent white cements from calcined sulphate of lime. October 22.

19,622. J. A. Yeadon and W. Adgie. Improvements in the manufacture of cements or other analogous materials. November 1.

19,716. J. L. Rawbone. An improved compound or treatment of clay to produce a compound for modelling designs. November 2.

19,813. O. Böklen. Improved process for making cement or cement mortar. Complete Specification. November 3.

19,908. C. G. Pickling. Improvements in or relating to fireproof buildings. Complete Specification. November 5.

19,947. W. Gutmann de Gelse. Process for preserving timber. Complete Specification. November 5.

20,132. H. D. E. Earl. Improvements in paving for streets, roads, and other places. November 9.

20,414. P. A. Moreau. The manufacture of variegated or veined artificial stone and imitations of natural marble. Complete Specification. November 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

22,111. E. Nelson. Material for use as a damp course in building foundations. November 2.

1892.

16,911. E. Edwards.—From K. Goetz. Process for producing liquid clay or slip for casting in moulds. October 26.

X.—METALLURGY, MINING, ETC.

APPLICATIONS.

18,892. F. O'Connor Prince.—From J. Dixon, F. J. Blades, W. S. Douglas, and D. Garlick, South Australia. Improvements in and connected with the smelting of the sulphurets or sulphides of certain metals, and in apparatus to be used therewith. October 21.

18,928. G. L. Morris and J. Williams. Improvements in machinery and appliances for coating metal sheets with tin, terne, and other metals or alloys. October 22.

19,125. J. Kirkwood. Improved process and apparatus for separating iron, silicon, and such like impurities from other metals and alloys. October 25.

19,155. W. A. Baldwin and F. G. Wheeler. An improved method of and apparatus for decarbonising iron. Complete Specification. October 25.

19,175. A. J. Boulton.—From F. Grassmann, Belgium. Improvements in or relating to the fining of pig or crude iron. October 25.

19,215. C. M. Pielsticker. Improvements in the method and apparatus for coating metal with a protective covering. October 26.

19,330. N. J. F. Romanet du Caillaud. An alloy for use in textile machinery. October 27.

19,361. A. S. Ford. An improved process of electroplating glass, china, &c. October 28.

19,371. W. P. Thomas and R. Davies. Improvements in coating metal plates or sheets with tin, terne, and other metals, and apparatus therefor. October 28.

19,467. J. Clark and G. W. Clark. Improvements in or relating to the manufacture of steel and iron. October 29.

19,600. J. Buchanan, jun. Improvements in apparatus for charging furnaces with metal. Complete Specification. November 1.

19,727. H. J. Phillips. A process for the elimination of sulphur and phosphorus from molten iron or steel. November 2.

19,769. E. Hunt.—From B. Hunt, Mexico. Improvements in cyanide processes for extracting precious metals from ores. November 3.

19,801. W. S. Rawson and Woodhouse and Rawson United, Limited. Improvements in and in connection with pickling and preparing iron or steel plates for tinning or galvanising. November 3.

19,844. H. S. Denny and J. T. Garrick. Improved process for the recovery of gold and silver and utilisation of by-products from ores containing the sulphides of antimony, arsenic, tin, zinc, lead, and copper, either individually or collectively. November 3.

19,845. H. S. Denny and J. T. Garrick. Improved process for recovery of gold and silver from their ores. November 3.

20,014. H. Pidot and H. Charlier. A new process for hardening cast iron, and manufacturing cutting tools or other articles of tempered cast iron. November 7.

20,025. F. G. Fuller. Improvements in the treatment of ores and recovery of metals contained therein, and appliances therefor. November 7.

20,040. C. H. Ridsdale and The North-Eastern Steel Co., Ltd. Improvements in the manufacture and treatment of ingot iron and steel. November 7.

20,151. H. H. Lake.—From R. W. F. Abbé, United States. An improved process for treating oxidised or corroded lead, and apparatus therefor. Complete Specification. November 8.

20,189. F. Feldhaus and J. C. Ollaguiet. A process for augmenting the resistance of iron, steel, and other metals. November 9.

20,208. W. A. Briggs.—From J. W. Richards, United States. An improved solder for aluminium. Complete Specification. November 9.

20,318. A. Guthrie and R. F. Macfarlane. Improvements in the treatment of complex ores containing sulphides of zinc, lead, iron, copper, silver, gold, or other metals. November 10.

20,419. Woodhouse and Rawson United, Lim., and W. S. Rawson. Improvements in pickling iron and steel plates and apparatus therefor. November 11.

20,430. I. J. Monger and R. Monger. Improvements in means or apparatus for use in smelting copper or copper-producing materials. November 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

19,573. G. Selve. A process of separating cobalt from nickel. November 2.

1892.

1443. R. B. Thomas. Coating sheets or plates of iron and steel with lead. November 9.

8612. E. H. Saniter. Purification of iron or steel. November 2.

16,168. K. Wittgenstein. Process for manufacturing thin steel or iron sheets direct from ingots or welded faggots. November 9.

17,908. W. Smethurst. New or improved furnace for the reduction or smelting of zinc, lead, silver, gold, and other ores. November 16.

17,928. C. H. Hubbell. Manufacture of mineral wool. November 16.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

18,807. E. Andreoli. Electrodes for secondary batteries. October 20.

18,817. J. A. McMullen. Improvements relating to galvanic batteries. October 20.

18,844. H. Koller. Improvements in dry cells or galvanic batteries. October 20.

18,966. Siemens Bros. and Co., Lim.—From Siemens and Halske, Germany. Process for the electrolytic decomposition of compounds of metals and sulphur. October 22.

19,170. H. Blackman. Improvements in the production of chlorine, soda, and other products by electrolysis, and in apparatus employed therein. October 25.

19,220. E. Freund.—From E. Freund, Austria. Improvements in electric batteries. October 26.

19,236. G. Wilkinson. Improvements in and relating to the generation and distribution of electrical energy. October 26.

19,282. W. Walker. An improvement in or connected with galvanic batteries. October 27.

19,393. T. Froggatt. Improvements in electric battery apparatus. October 28.

19,451. H. F. Joel. Improvements in voltaic batteries, electrodes, and connections. October 29.

19,655. H. G. O'Neill. See Class II.

19,880. T. Parker and A. E. Robinson. The manufacture or production of an improved anode for use in electrolytical processes. November 4.

19,953. J. C. Richardson. Improvements relating to the construction of electrodes for electrolytical purposes. November 5.

20,348. R. J. Black. Improved electric-battery cells. November 10.

20,489. A. B. Woakes. Improvements in apparatus for sterilising and oxidising liquids by electricity. November 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

18,477. O. Schlesinger. A depolarising liquid for galvanic batteries. October 26.

21,959. E. Hermite and A. Dubosc. Apparatus for the manufacture of alkaline or earthy alkaline bases and of their salts or compounds by electrolysis of saline solutions. November 2.

22,339. N. Wladimiroff. Primary and secondary batteries. November 9.

22,708. W. Helesen. Manufacture of porous carbon for galvanic batteries and for filters. November 2.

1892.

372. N. Benardos. Soldering, melting, and coating metals by the aid of electricity. November 16.

16,461. W. Main. Secondary batteries. October 26.

16,822. T. Craney. Electrolytic apparatus. November 16.

17,222. W. P. Thompson.—From C. L. Coffin. Electric metal working or welding. November 2.

17,223. W. P. Thompson.—From C. L. Coffin. Welding or working metals electrically. November 2.

17,225. W. P. Thompson.—From C. L. Coffin. Method and apparatus for electrically welding metals. November 2.

17,226. W. P. Thompson.—From C. L. Coffin. Method or apparatus for working or heating metals electrically. November 2.

ERRATUM.

20,312 of 1891 (p. 861). Erroneously announced as completed in Official Journal, 28 September 1892. Please cancel.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

APPLICATIONS.

18,527. J. Brown. Improvements in the manufacture of soft soap. Complete Specification. October 17.

18,533. J. Brown. Improvements in the manufacture of hard soap. Complete Specification. October 17.

18,744. A. Teal. An improved method of and apparatus for brightening rape, linseed, and similar oils. October 19.

18,918. I. R. Burns. Improvements in the manufacture of lubricating grease. October 21.

19,191. J. W. Chenhall and W. S. Chenhall. Improvements in effecting the solidification of mineral, vegetable, and animal oils and fats. October 25.

19,745. C. H. Freyer.—From F. Korn, Germany. The "Excelsior" oil-purifying apparatus. November 2.

COMPLETE SPECIFICATION ACCEPTED.

1892.

16,527. W. R. Lake.—From W. T. Cutter. Cleansing or extraction of fatty substances from wool and the like, and method of clarifying the solvent used therefor. November 15.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

APPLICATIONS.

15,735. H. H. Lake.—From L. Enricht, United States. An improved manufacture of paint or cement. October 19.

19,453. J. E. Hartley and H. E. Hartley. A new or improved dead or non-glossy coating or varnish. October 29.

19,536. C. H. J. Donnadien. An improved process of manufacturing turpentine. October 31.

19,539. J. F. Thompson and C. F. Baker. An improved colouring and burnishing composition for boots and shoes. Complete Specification. October 31.

20,456. H. P. T. Denny and W. L. L. Grant. An anti-fouling and protective paint for preserving the bottoms of iron or wooden vessels and other submerged surfaces. November 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

22,334. W. R. Harp. Material which may be used in arts and manufacture in the steel of india-rubber, gutta-percha, and other similar substances, and process for making the same and for the utilisation thereof of waste liquors from tanneries. November 3.

1892.

17,655. J. Birbridge. Preparing variegated rubber for manufacturing purposes. November 9.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATION.

29,351. C. S. Roy and C. S. Sherrington. A new and improved process for obtaining blood albumen for commercial purposes. November 11.

COMPLETE SPECIFICATION ACCEPTED.

1891.

21,527. T. J. Haslam. Substitute for whalebone. November 16.

XV.—AGRICULTURE AND MANURES.

APPLICATION.

18,648. J. Carter. Improvement in manufacturing manure from sewage. October 19.

XVI.—SUGARS, STARCHES, GUMS, Etc.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

19,762. R. Morton and T. Morton. Pans for boiling or heating sugar or compounds thereof or similar substances. October 26.

20,887. D. Stewart. Evaporating or concentrating saccharine liquids and apparatus therefor. October 26.

1892.

15,816. C. M. Lafontaine. New or improved process and apparatus for the treatment and purification of raw sugar, and its conversion into blocks or ingots. October 26.

XVII.—BREWING, WINES, SPIRITS, Etc.

APPLICATIONS.

15,697. G. Morris and J. H. Howell. Improvements in attenuators and skimming appliances for use in brewing and fermenting vessels. October 19.

19,814. C. F. H. Hallett. An improved refrigerator or heater for cooling or heating wort or other liquid. October 20.

18,911. H. Gardner.—From Van Laer, Belgium. Improvements in or connected with apparatus for the cultivation of pure yeast. October 21.

15,941. W. A. Swain. Improvements in strainers for the purification of malt liquor or other liquids. October 22.

19,254. A. Brin. An improved process of flavouring, impregnating, or modifying alcoholic liquids. October 26.

19,260. A. Brin. An improved process of distilling and rectifying alcoholic liquids. October 26.

19,261. A. Brin. Improved apparatus for distilling, rectifying, flavouring, or modifying alcoholic liquids. October 26.

19,535. B. Dukes.—From E. Briesemeister and W. A. Seyblich, Germany. Improvements in the manufacture of grape sugar. October 31.

20,295. W. S. Squire. Improvements in the manufacture of yeast. November 10.

20,317. A. Kerchbaum, F. J. Z. B. Strassnick, and R. Schmiedel. Improvements in the manufacture of malt liquor. Complete Specification. November 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

22,248. J. Pullman and H. S. Elworthy. A method of and appliance for the collection, purification, and utilisation of carbonic acid gas given off during fermentation of saccharine and other substances. October 26.

22,399. W. P. Thompson.—From O. E. Nycander. Preparation of extracts for use in the manufacture of yeast and spirit. November 2.

1892.

301. H. Prior. Apparatus for cooling and attenuating beer during fermentation. November 2.

17,254. E. Adam. Malt beverages. November 2.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

APPLICATIONS.

A.—Chemistry of Foods.

18,535. R. W. Leftwich. Improvements in cocoa and chocolate. October 17.

20,095. C. H. R. Christie.—From C. J. Christie, Argentine Republic. Improvements in and connected with the treatment of milk. November 8.

20,202. T. Hyatt and T. Rickett. See Class VII.

B.—Sanitary Chemistry.

18,598. F. P. Candy. See Class VII.

19,198. R. Stanley. An improved method for the purification of sewage waters and waters from chemical and other manufactures. October 26.

19,247. W. D. Scott-Moncrieff. Improvements in or relating to the treatment of sewage. October 26.

19,587. F. P. Candy. Improvements in the treatment of sewage and polluted waters, and in connection with the manufacture of materials for use in the treatment of sewage and polluted waters. November 1.

19,783. A. S. Ramage. Utilisation of human excreta. November 3.

19,785. W. Oldfield. Improvements in the method of purifying sewage and trade effluents. November 3.

19,829. L. Archbutt and R. M. Deeley. Improvements in apparatus for purifying water. November 3.

19,830. R. M. Deeley and L. Archbutt. Improvements in apparatus for purifying water. November 3.

19,866. J. Hanson. Improvements in means or apparatus for cooling and purifying liquids discharged from works or the like. November 4.

C.—Disinfectants.

18,957. S. P. H. Statham. A new or improved disinfecting and deodorising paper. October 22.

19,277. W. G. Daniell. A new or improved composition for preserving articles of food, and for disinfecting and purifying purposes. October 27.

COMPLETE SPECIFICATIONS ACCEPTED.

A.—Chemistry of Foods.

1891.

20,694. B. Corrick. New or improved manufacture of substances or compositions for use as condiments. November 9.

1892.

16,548. C. Blackmore. Process for incorporating malt, or the aroma therefrom, with coffee, tea, and similar substances used as a beverage or food. November 2.

B.—Sanitary Chemistry.

1891.

17,844. A. Wollheim. Plan for the construction of works for the treatment of sewage and other foul or waste liquids. October 26.

20,682. J. Price. Treatment of sewage. October 26.

1892.

16,333. W. F. Goodhue and C. Paulus. Apparatus for filtering and purifying sewage or other matters. November 2.

C.—Disinfectants.

1892.

16,202. G. S. Yingling, J. K. Pfaltzgraff, and G. K. Pfaltzgraff. Chemical compound for treating tobacco. November 9.

XIX.—PAPER, PASTEBOARD, Etc.

APPLICATIONS.

19,675. F. Greening, jun. Improvements in the manufacture of compositions and treatment of the base nitro-cellulose or pyroxiline for various commercial uses. November 1.

20,290. P. Smith. Improvements in apparatus for the manufacture of paper. November 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

19,135. L. E. Vial. See Class V.

1892.

477 G. Hagemann. Manufacture or production of cellular substances suitable for paper-making and fibre suitable for spinning. November 16.

XX.—FINE CHEMICALS, ALKALOIDS ESSENCES, AND EXTRACTS.

APPLICATIONS.

19,329. L. F. Riedel. A new compound or derivative of para-tolyldimethyl pyrazolon, and process for obtaining the same. Complete Specification. October 27.

19,648. L. F. Riedel. Manufacture of para-phenetol-carbamide. November 1.

19,878. H. Thoms. Process for obtaining *p*-phenetol-carbamide. Complete Specification. November 4.

20,497. P. A. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of new pharmaceutical compounds. November 12.

20,498. C. D. Abel.—From The Haarmann and Reimer Vanillin-Fabrik, Germany. Manufacture of β -cymidine, $C_9H_3(CH_3 \cdot NH_2 \cdot C_3H_7) \cdot (1:2:4)$ from the orims (oximes) of certain camphor species. November 12.

20,499. C. D. Abel.—From The Haarmann and Reimer Vanillin-Fabrik, Germany. Manufacture of mono-carbon acids having the composition of $C_9H_{14}O_2$, of di-carbon acids having the composition $C_9H_{14}O_4$, and of anhydrides of the latter having the composition $C_9H_{12}O_3$. November 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1892.

361. C. D. Abel.—From C. F. Boehringer and Söhne. Manufacture of vanillin. November 9.

16,942. W. P. Thompson.—From R. Campani. Process for extracting iodine from natural saline waters, mother-liquids, or other liquids containing iodine. November 2.

XXI.—PHOTOGRAPHIC PROCESSES AND MATERIALS.

APPLICATION.

19,531. H. J. Shawcross. Improvements in or connected with the production of sepia or like coloured photographic pictures and sensitised paper films and other media therefor. October 31.

XXII.—EXPLOSIVES, MATCHES, Etc.

NOTICES.

Members are reminded that the subscription of 25s. for 1893, payable on January 1st next, should be sent in good time to the Treasurer in order to ensure continuity in the receipt of the Society's Journal. Any changes of address to appear in the new List of Members now in course of preparation, should reach the General Secretary not later than January 15th, 1893.

Post Office Orders should be made payable at the General Post Office, London, to the Honorary Treasurer, E. Rider Cook, and should be forwarded to him at Bow, unless it be desired to notify a change of address.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Secretary is prepared to offer 5s. apiece for copies of the Society's Journal for January 1893 in saleable condition.

LIST OF MEMBERS ELECTED, 23rd DECEMBER 1892.

Amundale, C. J. P., The Briary, Shotley Bridge, Co. Durham, paper manufacturer.
 Bruce, Geo., 11, New Gravel Lane, Shadwell, E., analyst's manager.
 Bruckmann, Gustave T., 192, 18th Street, Brooklyn, N.Y., U.S.A., chemical engineer.
 Danglade, Ernest, Vevay, Indiana, U.S.A.
 Dunn, Fred., Plinders Lane, Melbourne, Victoria, analytical chemist.
 Fellowes, F. W., 61-62, Chancery Lane, London, W.C., brewer's chemist.
 Goodall, Walter, Alma House, Pudsey, near Leeds, analyst.
 Hopkins, Erastus, 12, Linden Street, Worcester, Mass., U.S.A., chemist.
 Karlsake, Wm. J., State College, Centre Co., Pa., U.S.A., assistant in chemistry.
 Langer, Dr. Carl, 5, Redesdale Terrace, Canfield Gardens, N.W., analytical chemist.
 Rhodes, Jos., Blane Cottage, Blanefield, near Glasgow, printworks chemist.
 Roberts, Ernest H., 15, Herndon Road, East Hill, Wandsworth, S.W., analyst.
 Selkirk, Wm., Beckermest, via Carnforth, mining engineer.
 Southern, Thos. Jr. Jr., Wheathill Chemical Works, St. Simon Street, Salford, manufacturing chemist.
 Stone, Wm., 315A, Swanston Street, Melbourne, Victoria, analytical chemist.
 Whitehead, Jas., 266, Liverpool Road, Patricroft, Manchester, dyer.

CHANGES OF ADDRESS.

SESSION 1892-93.

1893:—

Monday, Jan. 9th:—

Mr. Arthur G. Green, F.I.C. "Quantitative Analysis of Artificial Colouring Matters."

Mr. Bernard Dyer, D.Sc., F.I.C. "Notes on the Proportion of Fatty Acids in Oil Cakes."

Mr. Watson Smith, F.I.C. "Further Notes on the Preparation of Nitrous Oxide."

Monday, Feb. 6th:—

Mr. Oscar Guttman. "The Manufacture of Nitric Acid."

Mr. C. C. Hutchinson, F.I.C. "A New Form of Laboratory Filter Press."

Meeting held Monday, 5th December 1892.

MR. WM. THORP IN THE CHAIR.

ON THE ELECTROLYTIC PRODUCTION OF CHLORINE AND SODA.

BY C. F. CROSS AND E. J. BEVAN.

THE electrolytic production of caustic soda and bleaching powder has of late years occupied a good deal of attention. The subject is one of very considerable technical interest, and the commercial future of electrolysis in this direction of application being at the present time under serious discussion, we have availed ourselves of an opportunity of bringing the matter before the Society.

The problem of the economical manufacture of alkali and bleach by the electrolysis of salt solution is a very enticing one, and for many years past it has attracted the attention of inventors. It is, however, only within the last few years that any considerable advances have been made.

The chief difficulties have hitherto been (1) the devising of a diaphragm of such low resistance as would allow the electrolysis to proceed with a reasonably low electro-motive force, and which would at the same time effectually prevent the recombination of the products of electrolysis; and (2) the construction of an anode which would stand wear and tear.

These difficulties have, we venture to think, been very largely overcome, and we think there is a fair prospect of success in the near future.

We do not propose in the present communication to advocate any one of the many processes that are before the public, but to discuss the problem in general terms in the hope that we may be able to show the feasibility of an economical electrolytic process.

We shall, however, have occasion to describe somewhat in detail two processes with which we have had some practical experience. These are the Greenwood and the Le Sueur processes, and their essential features are shown in the diagrams on the wall.

In the former, the electrolyser consists of a rectangular tank of slate or other suitable material divided into compartments by means of diaphragms. These are made of a number of V-shaped shelves of glass or slate placed in a mahogany frame. The spaces between the shelves are filled with asbestos. On one side of the diaphragm is the cathode made of iron, and on the other side is the anode. This is of peculiar construction, being built up of a number

of pieces of hard retort carbon cemented together by first impregnating with tar and subsequently heating to a high temperature. The inside is filled with type metal. The cathodes and anodes in every electrolyser are connected together in parallel, the electrolysers themselves being in series. Arrangements are made by means of pipes for allowing the salt solution, which is about half saturated, to flow through all the anode and cathode sections respectively.

The chlorine which is evolved passes into the chlorine main. The caustic solution, after passing through a sufficient number of electrolysers, is evaporated, and the excess of undecomposed salt removed. The subsequent treatment of the chlorine calls for no special remarks.

In the Greenwood process no arrangement is made for the renewal of diaphragms or anodes, as both are believed to be practically indestructible. Time, however, can alone settle this point.

In the Le Sueur process the arrangements are very different.

The electrolysers consist of an iron tank fitted with a sloping floor, on which rests the cathode. This is formed of a ring of iron filled with several pieces of iron wire gauze. Several small holes are drilled in the top part of the ring to allow of the easy escape of the hydrogen. The floor of the tank is also sloped for this purpose. The diaphragm rests on the cathode. It consists of two parts, viz., a sheet of ordinary parchment paper and a double sheet of asbestos cemented together by means of coagulated blood albumen.

The diaphragm being placed in position, the inner vessel of earthenware is placed on it, and by its own weight makes a watertight joint. There are usually 6-12 electrolysers in each tank. Inside the vessel has been previously placed the anode. This consists of pieces of ordinary retort carbon imbedded in a mass of lead, through which electrical contact is obtained.

The object of the lutes is of course to prevent escape of chlorine. The lute, which is made of porcelain, is in order that any one electrolyser can readily be electrically disconnected from the others in the same tank. Without this it would be necessary to remove the cell entirely if anything happened to go wrong with it.

The cell being in position, a saturated solution of salt is run into the outer vessel until it reaches just above the upper edge. The anode section is filled with similar solution to a level about half an inch above that of the solution in the cathode section. The object of this is to prevent any transference of solution from the outer to the inner vessel, this being more harmful than the reverse.

The diaphragms are renewed every 48 hours; to effect this the whole of the inner vessels in any tank are simultaneously raised.

As the carbon of the anodes wears away they are lowered by means of the screws, so as to bring them as near as possible to the cathodes. After working for 6-8 weeks they have to be renewed. For this purpose the cells are taken to pieces and the lead melted and recast.

When the electrolysis has been continued long enough for the solution of caustic to reach a strength of about 10 per cent., the liquor is run away and the alkali precipitated as bicarbonate.

Having now briefly described the Greenwood and Le Sueur apparatus, we will proceed to discuss the problem from the point of view of cost. In doing this we shall base our estimates on figures obtained from the actual working of the Le Sueur system on a scale of half a ton of bleaching powder per day.

With the exception that the cost of plant would vary with every process, the figures may be taken as fairly representative of other processes.

In calculating the cost, the most important item is the power. Opinion varies considerably as to the cost of a horse-power; we believe, however, that it may fairly be taken at not more than $\frac{1}{4}$ d. per hour. We arrive at this estimate in the following way:—

Taking as our basis an output of 2,400 indicated horse-power hours, employing two engines of 1,200 horse-power each.

Cost of power per 24 hours:—

1. Coal.—Thus, with modern engines, we may safely take at 2½ lb. per horse-power hour.	£	s.	d.
2,100 × 2½ × 24 hours = 64 tons at 10s.	32	0	0
2. Labour.—8 day men and 8 night men, at 30s.	1	0	0
3. Depreciation at 10 per cent, for 300 days on			
Engines	10,000	0	0
Boilers	7,000	0	0
	£17,000	0	0

4. Oil, waste, &c.	1	0	0
	£42	10	0

12l. 14s. 08. = 10,392 farthings, which, divided by 24 hours and again by 2,100 horse-power gives us 0.771 of a farthing as the cost of one horse-power hour.

At this point it may be interesting to quote the estimate given by Dr. John Hopkinson. In an address recently delivered to the Junior Engineering Society, this authority states his opinion that a Board of Trade unit (1,000 watts) can be produced at a cost of one-third of a penny, which is as nearly as possible equal to 1 farthing per horse-power hour.

Now this 2,400 horse-power when converted into electrical energy and delivered at the terminals of the electrolyzers will be equivalent to only 2,000 electrical horse-power on the basis of a loss in conversion and leakage of 17 per cent.

We now have to consider what amount of electrical energy can be got from 2,000 electrical horse-power. This, of course, will depend on the electro-motive force at which the current is employed. In practice, it has been found that with arrangements, such as the Greenwood and Le Sueur processes offer, the decomposition of the salt can be effected with a current working at 4½ volts. As a matter of fact, 3 volts or less is sufficient, but in that case the amount of decomposition per unit of plant, if we may use the expression, is small, and the saving of power thus effected would probably be more than counterbalanced by the standing charges on the extra plant required. 2,000 electrical horse-power × 746 = 1,492,000 watts. Dividing this by 4½ volts we arrive at a current of 331,555 amperes equal to 7,957,320 ampere hours.

Each ampere hour is theoretically capable of producing 0.00292 lb. of chlorine, therefore 7,957,320 × 0.00292 = 23,235 lb. of chlorine per 24 hours. Taking a practical efficiency of 80 per cent, we find that our current of 331,555 amperes will yield 18,588 lb. or 8.3 tons of chlorine per 24 hours, equal to 22.43 tons of bleaching powder containing 37 per cent. of chlorine.

Each ampere hour will yield 0.0033 lb. of caustic soda (NaOH). Going through a similar calculation we get a yield of 9.378 tons of caustic soda or 12.426 tons of ash per 24 hours.

These products at present selling prices would be worth—

22.43 tons bleach at 7l. 10s.	£	s.	d.
9.378 tons caustic at 12l.	168	4	6
	112	10	0
	£280	15	3
22.43 tons bleach at 7l. 10s.	168	4	6
12.426 tons ash at 5l. 15s.	71	9	0
	£239	13	6

Now as to the cost of production. This we arrive at in the following way:—

Cost of production of 23 tons bleaching powder and 9.378 tons of caustic or 12.426 tons ash per 24 hours:—

18 tons salt at 12s.	£	s.	d.
12 tons lime at 12s.	10	16	0
Power, 2,400 × 24 = 57,600 horse-power hour at ½d.	7	4	0
Labour	60	0	0
Casks and packages	10	0	0
Depreciation at 10 per cent, for 300 days on—	18	0	0
Electrolysers	£	s.	d.
Dynamoes	12,000	0	0
Tanks, pumps, buildings, &c.	8,000	0	0
	10,000	0	0
	£30,000	0	0
	10	0	0
Superintendence	1	0	0
General expenses	1	0	0
	£121	0	0

Where the diaphragms and anodes require renewal, as in the Le Sueur system, a further sum must be added. This will amount to 30l. The carbonic acid for converting the caustic into carbonate, we may put at the outside figure of 2l. We arrive at a total cost of production of 153l.

When caustic soda is the product required it will be necessary to increase the cost of production by the expense of evaporation. This should not amount to more than 1l. per ton. It is probable that even with the most perfect anodes and diaphragms a certain sum will have to be put aside for renewals. What this should be experience only can tell. Where the rate of disintegration is known, as in the Le Sueur system, it can be fully discounted.

It must also be borne in mind that caustic soda obtained by evaporation of solutions of salt and soda still contains a certain amount of salt, which will render it less valuable than purer products. The margin of profit is, however, sufficiently large to allow for such contingencies.

Such then is briefly the present position of electrolytic soda and bleach. We have tried to show that under by no means extravagant conditions they can be produced at a price which at the present selling prices leaves ample margin for profit.

It may be of interest to members of the Society to know that the Le Sueur process is now in operation at Rumford Falls, U.S.A., on a scale of 3 tons of bleach per day. We may also mention that the Hermite Electrolytic Bleaching Process, which we had the honour of bringing before the notice of the Society in 1887, and to prove the utter absurdity of which a considerable amount of energy was devoted by a distinguished authority, has proved itself highly successful on the Continent. At the present moment it is replacing 3,000 tons of bleaching powder per annum.

Notwithstanding the very confident predictions of certain authorities as to the utter impossibility of an electrolytic soda process paying, we venture to think it is destined to play a very important part in the future development of the alkali industry.

DISCUSSION.

Mr. W. T. Reto said that he had taken a good deal of interest in this subject. He had watched the operation of the Greenwood process, and the result of his observations was this, that he knew alkali was produced. He had heard it said that it could not be made by the electrolytic method. But there was no doubt that it was produced chemically by the process described. There were, however, some points not mentioned in the paper, which he had observed, and he thought it would be well if these points were discussed. One of them was the by-products which were produced. This was a very important matter. During the electrolysis of chloride of sodium a considerable percentage of other matters than caustic soda was produced, especially chlorate of soda. Another by-product which was produced to a considerable extent was hydrogen. As soon as the current was turned on they saw a very copious evolution of hydrogen, so copious that it might be used as a source of heat to evaporate the liquors afterwards. Still at the same time this would involve a loss of power, as they could get that heat by a very much better process. They saw on the table before them one of the anodes used, and it was a very ingenious way of getting over the difficulty. Such anodes lasted a long time, but they did not last for ever. They had in one process a certain amount of retort carbon which lasted a definite time, he thought it was mentioned as being from six to eight weeks. A certain percentage should be allowed for the renewals of these anodes. The diaphragms were as perfect as they could be made. They worked extremely well, and the asbestos stood very well indeed. With regard to the diaphragm in the Le Sueur process, it was rather troublesome to change it so frequently as once in the 48 hours. It added to the cost of production and seemed to be a great disadvantage. Then again, the outer vessels in that process were rather liable to be acted upon. He did not think the cast iron would be a permanent substance in connection with these liquids. Then it had not been mentioned in connection with

extracting caustic soda how that soda could be got in a commercial form. The liquid was rather dilute and there was with it not only the residual chloride of sodium but also the chlorate of soda and other substances, and they had to boil all these substances down and extract the chloride from them before they could make use of it. The chlorate of soda and other by-products would be concentrated in that solution as they returned it for electrolysis again; so that there would be a continual accumulation of the by-products. With regard to the strength of current, he thought that although Mr. Greenwood had said that a certain current was the best under certain conditions, the whole question had got to be worked out. He thought any estimate as to the cost of energy based on present data would be, to a certain extent, hypothetical. There was no doubt in his mind that the cost of producing caustic soda by the electrolytic process would be very much less than that of producing it by any other process. Given electrical energy at a cheaper rate, and electrolytic soda would completely supplant soda produced by the ammonia process and other methods.

Mr. BERTRAM BLOUNT said that the impression made on his mind when he inspected the process at the beginning of the year was that the diaphragm was a very ingenious apparatus, and that the anode had been devised with great care; but he remembered asking Mr. Greenwood at that time whether he made any attempt to deal with one of the by-products mentioned by the last speaker, viz., the hydrogen. By the production of that body part of the energy was lost; and if it could be suppressed and the restitution of the energy accomplished, or if some industrial use could be found for it, it would be a distinct advantage. Whether this was possible or not he could not say, but possibly the authors, who had been intimately connected with the process for some time, would be able to give them some information on the point. He would, therefore, ask them to say whether any attempt had been made to use the hydrogen or suppress it.

Mr. W. CROWDER inquired whether the process was at work in London, and whether on an experimental or a practical scale.

Mr. BEVAN replied that it was in operation in London on an experimental scale at present, but that a company was being formed to work it on a large scale.

Mr. P. MACEWAN said that when he saw the process at work he understood from the gentleman who had explained it to him that 10 per cent. only of the salt was decomposed; therefore, they had to add 90 per cent. of waste to the figures which had been given in the paper. The expense of working it was very great, for he was informed that a man was engaged in doing nothing else but plying a small brush to keep the joints of certain parts of the machinery cleared; and he wished to know whether that would be the case in actual working. He might remark that he was not interested in any of these electrical enterprises. He understood that the process before them was likely to be adopted only by paper-makers and other people who used caustic soda in solution. In fact, the expense of removing the salt, and evaporating the solution after in order to get caustic soda for commercial purposes, would be quite equal to the ordinary cost of producing it by the Leblanc process. Where, therefore, was the advantage? He thought that the figures on the tables before them were hardly reliable, and must be taken with a good deal of reserve, especially in view of the fact that the selling prices quoted were the prices of bleach and caustic in London.

Mr. CROWDER said that if it was a fact that a certain quantity of soda, and certain products, were made by the process in America, he wished to know whether this was done under the circumstances described, and at the cost quoted, or under those which Mr. MacEwan had spoken of.

Mr. SYDNEY EVERSLED wished to call attention to one or two features of the paper from the point of view of an electrical engineer. The authors had referred, as one or two of the speakers had done, to the economy of production

of electrical energy. He did not think there was very much hope of the production of electrical energy at a lower rate than as carried on now in many of the central stations supplying the electric light in London, and he must say that the figures given on the blackboard seemed to him very fair and reasonable. He would point out that engines might be produced, and were being produced now, to give an indicated horse-power for considerably less than $2\frac{1}{2}$ lb. of coal per hour; he believed he might say at 1.8 lb. per indicated horse-power. They had to transform that indicated horse-power into electrical energy, and that was being done at the central stations in London at an efficiency of 85 per cent. When they came to deal with the consumption of that energy, it was rather astonishing to him to find that the inventor of the process willingly sacrificed more than 50 per cent. of the power (Mr. Cross: "No, no"). He thought that the author of the paper said that $4\frac{1}{2}$ volts were used in the electrolyser. He was speaking off-hand, but he thought that the electromotive force of decomposition of the solution was something like 2 volts. He would like to be informed whether that was so or not (Mr. Cross: "Yes"). He need hardly remark that the electromotive force of decomposition multiplied by the force of the current gave the useful energy of the current, while the remaining energy was spent in overcoming resistance, and it certainly seemed possible that the energy so spent might be looked to in future for reducing that amount of 60% which figured so largely in the authors' estimate.

Mr. A. SHEARER wished to know on what data the figures given had been arrived at, whether the process had been carried out to the extent of actually making a ton of caustic soda—working to the bitter end—or whether they had assumed from certain short experiments that the desired end could be attained. If so, they were entirely wrong. If they took certain periods of time, for example, they would find that for the first six hours everything went on swimmingly; but if they carried on the process they would discover that at the fourth period of six hours they consumed nearly three times as much electrical energy as they used in the first; so that it was important to know whether these figures had been made up from one run of six hours or from the results extending over a period of time. If they had to make only a ton of caustic it would no doubt be a very different thing from carrying on the process continuously.

Mr. C. F. CROSS thought that the last speaker was the victim of the "practical" superstition. The high officials of Alkali Union were not people likely to trifle with a matter of this kind. He himself had the running of an official test of the Le Sueur process before their chemists, who were present, and they were asked to do such things as would satisfy those gentlemen. The only tests which they asked to be applied were as to the percentage of chlorine in the gases liberated and the contents in alkali and salt of the resulting solution, showing the absence of hypochlorites and similar bodies. He ran that test for 12 hours. Their efficiency curve was a straight line, showing that there was no falling off. They ran up to 5 or 6 per cent. of sodium hydrate and the test was at an end. Dr. Hurter never criticised them on any other hypothesis than the cost per unit of power. They knew that with a solution containing 6 or 7 per cent. of sodium hydrate and a definite proportion of common salt, the total cost of preparing a ton of caustic soda therefrom was a matter of simple calculation.

The CHAIRMAN thought that the figures on the blackboard showed a very comfortable margin indeed, but some doubts had been expressed as to whether that margin existed or not. It was a process that would require much working out, and it was in one sense, therefore, in the experimental stage. It had occurred to him that from a mixture of caustic soda and chloride of sodium containing only 10 per cent. of caustic it was very doubtful whether it would pay to separate the former. Perhaps the authors would be able to give some information on the point. Although it was pointed out that the prices given were the London prices of bleach and caustic, still they probably would not differ very materially from the prices in places where coal was cheaper. It was obvious, however, that the price quoted for coal was not a London price.

Mr. BEVAN, in reply, said, referring to Mr. Reid's remarks as to by-products, with a properly constructed diaphragm only a small quantity of hypochlorite or chlorate would be formed. After many hours' running of the Le Sueur process, the solution gave no reaction with starch paper. Eventually some hypochlorite might be formed, but this was not a very serious matter after all, because it was all accounted for in the 20 per cent. loss which they estimated. As regards the accumulation of the by-products as the salt went round and round, it would pay to throw away the salt occasionally; it was not a large item in the total cost. He did not know whether Mr. MacEwan was serious when he put his questions, but that gentleman had got an utterly erroneous idea as to the 10 per cent. decomposition. If the salt was not decomposed, it was there to be used again, and it was absurd to talk about 10 per cent. only being used. They had made every allowance for waste. Mr. Reid seemed to think that the evolution of hydrogen was a loss of power. There was no doubt about it. It must be. There was no other way, so far as he knew.

Mr. BLOUNT: It has been suppressed, I believe?

Mr. BEVAN replied that it had been suppressed in the Richardson process, and no doubt if arrangements could be made for utilising it, it would be a very considerable set-off against the cost of coal and the cost of power. Mr. Reid had mentioned that some allowance ought to be made for the disintegration of the anodes. He had not said they would last for ever. What he had said was that this anode as constructed was a very ingenious apparatus, and there was a strong probability of its lasting much longer than any anode that had ever yet been made; and as he had pointed out, in the Le Sueur system a very large allowance was made for this, and also for the diaphragms. Every loss was thoroughly accounted for, and the renewal of a diaphragm like this was made perfectly simple. He did not think there was any danger of the caustic solution acting on the outer vessel. As to the cost of electrical energy, Mr. Evershed had stated that the figures given in the paper were very fair. He (the speaker) was very glad to hear this from one who had given so much attention to the subject. That gentleman had spoken of 50 per cent. of the power being wasted. He (the speaker) pointed out that decomposition would take place at very much less than $4\frac{1}{2}$ volts, but in that case a very large plant would be necessary to produce a certain amount of caustic. They must have plant two or three times the size that they would have if they worked with $4\frac{1}{2}$ volts, so that it was found in practice that a current of $4\frac{1}{2}$ volts was the most economical to work with. As regarded the basis of calculation, certain of the numbers were of course hypothetical, because they had not—and nobody had—made 22·43 tons. The process was being worked at present at the Rumford Falls in America, on a scale of 3 tons of bleach per day, and arrangements were being made for working the Greenwood process. It was obvious that if they could make 3 tons at a profit they could make three millions. If they could do it on a big scale they could do it on a bigger, until they reached a gigantic enterprise. So far as he knew, 1 ton of electrolytic caustic soda had never been made in this country, but it was not necessary to show from the facts which he had given already that it might be done. Mr. Thorp had spoken of the process as being in the experimental stage. As he (the speaker) had said, it was being worked on a much larger scale than an experimental one, and no doubt as the work proceeded various improvements would be made. The process was sufficiently well developed now to induce large financial gentlemen in America to invest their money in it and to put up the works he had mentioned. With regard to the utilisation of a solution of 10 per cent. of caustic soda, he did not think that was a difficult matter. They must not forget that in the production of caustic by the Le Blanc process the solution was not much stronger, and a very large quantity of water must necessarily be evaporated. The caustic soda as it was made at present was at one time in a state of weak solution. He therefore did not think it was a difficult thing to deal with a 10 per cent. solution when the bulk of it—99 per cent.—could be thrown down as bicarbonate. With

regard to the prices quoted, he had taken them from the Chemical Trade Journal of that day, and they did not represent the prices in London; but then they did not propose to establish a manufactory in London. If London were in a less favourable position for working, they would go wherever local circumstances favoured them.

ON THE PRODUCTION OF ACETIC ACID FROM THE CARBOHYDRATES.

BY C. F. CROSS, E. J. BEVAN, AND J. F. V. ISAAC, B.A.

The chemistry of the carbohydrates has been greatly advanced in recent years, and the constitutional relationships of the members of this group are being rapidly elucidated.

While the finer points of molecular structure are being brought into the field of clear vision, and all the refinements of modern theory and method are being applied to the work of differentiating them, there is still much to be learnt in respect of the more general questions of molecular equilibrium common to the group. Thus the alcoholic fermentation of dextrose, which may be regarded, in a sense, as a property of the carbohydrate molecule itself, remains unexplained, as well as many other instances of molecular rupture of a similar character, similar in this respect, viz., that they may be regarded as determined by a migration of hydrogen atoms in the one, and of oxygen atoms in the other direction within the molecule. The production of lactic acid and of acetic acid from dextrose by the action of alkalis in dilute aqueous solution are decompositions of this order, and although they may be expressed, after the manner of text-books, by the simplest equations, viz.,—

it is known that they are very much more complex in fact.

To the latter of these changes, as a subject for investigation, we have been attracted on the ground of technical as well as theoretical interest.

During the progress of our research work on the general question of the formation of acetic acid in various decompositions of the ligno-celluloses, our friend Mr. W. H. Higgin, B.Sc., who had been independently investigating the subject from the technical point of view, took out a patent* for the production of acetate of soda from the alkaline waste liquors from straw and esparto boiling, and in the work of developing this process we have joined Mr. Higgin, and we shall have a few words to say on this new, or rather newly recognised, by-product of paper manufacture.

It will simplify the work of recording our investigations if we note a few of the theoretical considerations which have guided us.

The simpler carbohydrates appear to owe their characteristic properties to the one oxygen atom which they contain united to carbon atoms only, i.e., either as CO or C—O—C. If we take, as a general case, the following as the constituent groups of a molecule, CO(CHOH)₄CH₂, we should assign variable functions to the OH groups, according to proximity to the CO or acid grouping, or the CH₂ or basic grouping, and the equilibrium of such a body, or its hydrate, in aqueous solution would be somewhat similar to that of the salt of a weak acid and weak base. There are many reactions of dextrose and the carbohydrates generally in aqueous solution, or otherwise, which correspond with this view of their constitution. Thus dextrose combines in aqueous solution with bases such as lime, magnesium, lead oxide, and zinc oxide, giving well-defined compounds. It combines with acid radicles under dehydrating conditions, i.e., to form acid ethers or esters, and it also shows a tendency to combination with acids in aqueous solution. This is perhaps better seen, at least more easily demonstrated, in the case of the complex carbohydrates such as

* Eng. Pat. 13,469, 1891.

cellulose and its allies, which withdraw both acids and alkalis from aqueous solution, evidently as a result of reaction with the OH groups of the fibre substance, acid and basic. Direct evidence of combination of such carbohydrates as dextrose with acids in aqueous solution is afforded by the phenomena of acid hydrolysis, *e.g.*, the inversion of cane sugar. A. Wohl (Ber. 1890, 2086) has recently shown that this anhydride can be completely 'inverted' by treating with $\frac{1}{20,000}$ th of its weight of hydrochloric acid, and this result cannot be explained without assuming the occurrence of combination between the acid and the sugar molecules.

Lastly, we may cite the 'molecular' compounds which dextrose forms with neutral salts such as the chlorides and bromides of the alkali metals. These compounds are of the nature of double salts, and in their formation the saline character of dextrose in aqueous solution is apparent.

If we adopt this view, we may regard these carbohydrates in aqueous solution as under a species of electrolytic strain, and this is perhaps the simplest explanation of the mobility of oxygen and hydrogen within the molecule which we notice in the presence of exciting causes of such different character as the living yeast cell on the one hand and the alkaline oxides on the other. It is the latter condition with which we are concerned in the investigations we are about to describe.

We have subjected a number of typical carbohydrates to treatment with the caustic alkalis under various conditions with the object of determining—

A. The maximum yield of acetic acid.

B. Whether this maximum has reference to the constitution of the compound, and if so,

C. Whether the result confirms the view above elucidated.

Before describing our experiments in detail, we would premise that the method adopted for determining the acetic acid formed is exhaustive distillation and titration. The result was controlled in many cases by conversion of the volatile acids into silver salts in which the Ag was determined, and in all cases by examination of the distillate for the presence or absence of other bodies. The method of carrying out the decomposition was as follows:—The substance, generally in quantities of 2 grms., was mixed with the alkali dissolved in the minimum of water, and treated as described. The product was dissolved in water, the solution carefully acidified with sulphuric or phosphoric acid, and distilled.

A.—THE MAXIMUM YIELD OF ACETIC ACID.

1. Digestion of the Carbohydrates with Alkalis at 110° C.

The digestion of the carbohydrates with alkalis at a low temperature has already attracted the attention of several observers, but more especially from the point of view of the formation of lactic acid. Thus Kiliani (Ber. 15, 699) obtained lactic acid by heating together invert sugar and soda to 70° C. (see also Nencki and Sieber, J. Pr. Chem. 24, 498), and yields of 25 per cent. to 40 per cent. of this acid have been obtained under various conditions of digestion with weak alkali. The mechanism of this reaction does not appear to have been investigated. The reaction is complex, and the formation of other products has been noted. Amongst these we find acetic acid. Several experiments were made with cane sugar and with hydrocellulose at 100–110° C. Of these we give the results of two as typical.

Substance.	Potash.	Percentage, $C_2H_3O_2$.
Sugar	3:1	7.5
Hydrocellulose	3:1	14.0

Continuing these observations at 120°–150° C, and extending them to other substances, we obtained the following results, the alkali used being sodium hydrate (3:1):—

Substance.	Percentage, $C_2H_3O_2$.
Cane sugar	9.0
Cellulose (bleached cotton)	7.0
Hydrocellulose (cotton)	11.0
Jute	37.0
Pine wood ("wood-wool")	18.0

The formation of the relatively large quantities of acetic acid from the more complex, *i.e.*, the fibrous carbohydrate, is especially noteworthy.

It should also be noted, as of technical interest, that the alkaline liquors from linen cloth boiling, the temperature of which does not exceed 110° C., has been found to contain acetic acid, of which we have observed as much as 7 per cent., calculated on the organic matter in solution.

Experiments at 150° C.

The conditions of our next series of observations were as before, but potassium hydrate was employed as the alkali, and the temperature of digestion was kept constant at 150° C. The duration of the experiment was 48 hours. The yields obtained were as follows:—

Substance.	Percentage, $C_2H_3O_2$.
Cane sugar	16.0
Hydrocellulose	19.5
Jute	15.0
Wood	18.0

We must note here the bearings of these observations upon the general questions of the action of alkalis upon cellulose.

Thus Lange has proposed (Zeit. Physiol. Chem. 14, 217) as a method of estimation of cellulose in ligno-cellulose, *e.g.*, woods, a process of digestion with strong solutions of caustic alkalis at 185° C. Amongst the products of decomposition other than cellulose, which he assumes to be unaffected by the treatment, he notes the formation of formic and acetic acids. It is, however, quite clear, from our observations, that the cellulose molecule may be entirely decomposed under alkaline treatment of a certain degree of severity, and cannot remain unaffected under the conditions of treatment prescribed by Lange. As a method of estimating cellulose, it may therefore be dismissed.

Experiments at 200°–250° C.

The process of treating the ligno-celluloses (wood, sawdust, &c.) with the alkaline hydrates at this temperature is, as is well known, one of the standard methods for the commercial production of oxalic acid. An exhaustive investigation of the method was made some years ago by W. Thorn, and the influence of the several factors, time, temperature, nature of alkali, and proportion of alkali to organic substance, carefully determined in regard to yield of oxalic acid (Dingl. Polyt. J. 210, 24).

In this paper we find only a passing reference to the formation of acetic acid as a product of their decomposition. The greater number of our experiments have been made at this temperature. The heating in some cases was carried out on a sand-bath, in others we employed the form of air-bath described by Chorley and Ramsay in their recent paper (this Journal, May 1892).

At this temperature the decompositions are rapid, and the probable effect of atmospheric oxidation may be regarded as excluded. Under these conditions the maximum yields

from the several carbohydrates examined are approximately 33 per cent., as the following table shows:—

Substance.	Percentage, $C_6H_{12}O_6$.
Cane sugar	33
Milk sugar	31
Hydrocellulose	29
Jute.....	37
Pine wood	28

It appears in fact from these experiments—which are only a few from amongst the very large number carried out—that from all these carbohydrates we obtain about one-third of the molecule as acetic acid. Assuming these to be made up of C_6 units, each containing a CO_2CH_3 "residue," and the acetic acid to be a product of resolution, rather than of more complex reactions, the percentage yield would in effect be approximately 33 per cent. The results therefore are a satisfactory confirmation of the *à priori* view from which we started.

With regard to the remaining products of decomposition they are for the most part bodies of low molecular weight. Hydrogen is evolved in quantity, as is well known. In order to see whether this gas was accompanied by gaseous carbonic compounds, we carried out two experiments, in which the gaseous products, after passing through tubes filled with calcium chloride, were led over heated copper oxide, and the products collected in the usual way. In these experiments we employed cane sugar, 2 grms., KOH, 6 grms., water, 4 grms. Temperature 200–250° and we obtained—

	I.	II.
H_2O	0.610	0.434
CO_2	0.100	0.104

from which we get the approximate atomic ratios—

	I.	II.
$H:C$	30:1	20:1

and the conclusion that gaseous carbon compounds (CH_4 or CO) are only formed in relatively small quantity:—

It will be noted that the hydrogen evolved is about 2–3 per cent. the substance or from one-third to one-half the total.

Oxalic acid we found present in some quantity, much more being formed from the complex than from the simplex carbohydrates.

Thus, on heating for eight hours at 250° in a closed vessel, using three parts KOH to one of substance, we obtained the following yields:—

Substance.	Per Cent. $C_6H_{12}O_6$
Sugar	12.5
Hydrocellulose	41.7
Jute.....	59.3
Beechwood	58.0

Of bodies of higher molecular weight formed in the reaction one only appears to be specially characterised, that

is a compound dissolving to a strongly (orange-green) dichroic solution, of which we shall have more to say in a subsequent communication.

In the course of these experiments we have in certain cases obtained exceptionally high yields of acetic acid, which appears to be due to two causes:—(1) the prolonged duration of the heating; (2) to atmospheric oxidation. We have made a number of experiments in which oxidising agents have been added to the alkali-carbohydrate mixture. The results of these additions, of which we may mention potassium ferricyanide and ferric oxide have been, an increase of yield from the complex carbohydrates (fibre-substances) at the lower temperatures, *i.e.* 150° and below. Then in one experiment we took with 1.8 grm. hydrocellulose, 4 grm. NaOH and 4 grm. Fe_2O_3 in the form of the precipitated hydrate, and obtained after 48 hours heating at 150° 42 per cent. of its weight of acetic acid; whereas on heating with the alkali alone under similar conditions we obtained 20 per cent. only.

We mention this result as of some technical importance. The "terdering" of textiles produced by the joint action of alkali and iron oxide is a common experience of linen and cotton bleachers, and it finds some explanation in these observations.

In addition to the above we have also investigated the effect of addition of alkaline nitrates:—The mixture of cane sugar (2 parts) potassium hydrate (4 parts) and potassium nitrate (2 parts) with sufficient water to bring about an intimate mixture of the reagents, deflagrates at 140–150° if rapidly raised to that temperature.

If, however, the mixture be heated for some hours at 130°–140° the decomposition may then be finished at 200–250° without any explosive manifestations.

In this way we obtained 40 per cent. of its weight of acetic acid, and 2.5 per cent. of hydrocyanic acid. This transfer of nitrogen to carbon under the conditions of the experiment is its most noteworthy feature. The yield of acetic acid does not appear to be affected.

We have given our experimental evidence for regarding the acetic acid as formed in the primary decomposition of the carbohydrate; but it is obvious that there are secondary reactions which may contribute in this direction. To throw light on this point we have subjected other bodies having a "carbohydrate" formula ($C_nH_{2m}O_m$), *e.g.* lactic acid and phloroglucol, to alkaline fusion under the conditions described above.

"Fermentation" lactic acid in the form of the purified zinc salt heated at 250° for 6 hours with three times its weight of KOH gave 28 per cent. of acetic acid. Phloroglucol, similarly treated, gave 34 per cent. of its weight of acetic acid, and from the products of the fusion we recovered 33 per cent. of the original quantity unaltered. The yield of the acid, therefore, upon the weight decomposed is very high, as of course might be expected from other decompositions of this "aromatic carbohydrate."

The experiment was repeated, substituting sodium for potassium hydrate and the same yield of acetic acid, *viz.*, 34 per cent. was obtained.

With regard to the question of the oxidation of the alcoholic groups $CHOH$ and CH_2OH , we have so far investigated only one of the polyhydric alcohols of low molecular weight, *viz.*, glycerin. From this body, heated with three times its weight of sodium hydrate at 150° for 16 hours, we obtained but a small quantity of volatile acid, which gave none of the reactions of acetic acid; and the silver salt was found to contain 45 per cent. Ag (acetate = 64.7 Ag); evidently therefore an acid of much higher molecular weight (or a polybasic acid).

Experiments in the higher alcohols will be undertaken in due course, as the comparative evidence to be drawn from such observations is required to show conclusively the influence of the CO_2CH_3 residue—not present in these bodies—in determining the acetic decomposition.

To draw conclusions as to the influence of the several factors of the decomposition is, of course, one of the purposes of this investigation, but these we reserve for subsequent communications, in which also the carbohydrates of known constitution will be compared in regard to

yield of acetic acid. In regard to the influence of the alkalis, we may say, however, that our results confirm, for the production of acetic acid, those obtained by Thorn and others for oxalic acid, *i.e.*, the yield of acid is increased as the proportion of alkali to carbohydrate increases from 1 to 3. The yield is greater, *ceteris paribus*, with potash than with soda, and intermediate yields are obtained with mixtures of the alkalis. Generally the "potash fusions" are more fluid than with soda, and the molecular disintegration of the organic substance takes place at a lower temperature.

In conclusion, we have to say a few words upon the technical departure in the direction indicated by these results, independently initiated by Mr. W. H. Higgin. This chemist has patented the process of preparing acetate of soda from the waste liquors from pulp boiling in the paper works. Esparto liquor, for instance, is evaporated by any of the ordinary methods, and charred by heating on a floor, finishing the process by heating at 350°–400°. Acetate of soda is formed during this process, chiefly at between 150° and 200°, but the higher temperature, which does not affect the acetate under these conditions, is necessary for the complete carbonising of the fatty and waxy bodies, the presence of which interferes with the lixivation.

The course of the decomposition may be seen from the following statistics of the process:—

100 of esparto give:—

46 parts soluble with	
16 parts caustic	
62	Total solids.

100 of evaporated extract charred according to the process give:—

37.2 water, gas, and volatile	
38.0 soluble extract	
24.8 spent char	

The soluble extract contains the acetate, with a certain proportion of carbonate. The yield of the former is 5–6 per cent. ($\text{Na}_2\text{C}_2\text{H}_3\text{O}_2$) of the weight of the original esparto.

The spent char is composed of:—

Ash (50 per cent. NaO)	40
Sodium acetate	16
Carbon, &c.,	44
	<hr/> 100 <hr/>

This process has been worked experimentally on the large scale with satisfactory results, and the yields of acetate have been several times confirmed by independent observations.

Difficulties have, of course, been experienced in the working details of the process, but these are in a fair way towards being overcome.

With acetate of soda ($\text{Na}_2\text{C}_2\text{H}_3\text{O}_2 \cdot 3\text{H}_2\text{O}$) at 16l. to 18l. per ton, the unfortunate paper-maker of these latter days has a new objective opened out for the increase of profits, and we hope to see the recovery of this product established as a part of the routine of the paper mill.

DISCUSSION.

The CHAIRMAN said that he would like to ask Mr. Cross whether the presence of oxide of iron increased the bleaching action. He did not think that Mr. Cross had pointed out exactly the reason for this. Again, it seemed curious to him that such a substance as jute or cellulose should be treated as if it were a homogeneous body of definite composition. It might be uniform in composition, but the authors had seemed to deal with it as if it were a definite chemical substance. Further, with regard to the distillation of the acetates, was that process likely to be remunerative, apart from geographical considerations? He understood that it might be under certain conditions, but he wished to ask whether it would be a matter of general application?

Mr. WATSON SMITH thought that as acetate of soda cost 16l. to 18l. per ton, it would be interesting to know at what price these chars could be produced, containing acetate of soda at so much per cent., because then an idea would be given to the acetic acid manufacturer as to what he would be likely to have to pay for such residue at so much per cent. He would like to know whether Mr. Cross had experimented with the sulphite cellulose liquors obtained in the manufacture of paper pulp. A large quantity of such liquors was produced, and created an intolerable nuisance. They were generally allowed to run down the brooks, giving off most unpleasant odours. If these liquors could be evaporated down, he knew that they would yield a rich sort of gum of mixed character, having strong adhesive properties, though smelling disagreeably. He had never been able to discover an economical method of deodorising them. He thought it possible that by charring, acetic acid would be obtained.

Mr. F. G. ADAIR ROBERTS asked what was the percentage of the residue left after evaporation. Mr. Cross had mentioned that 37 per cent. was water and that there was 38 per cent. of soluble substances; but he did not state whether he examined what the residue consisted of, or whether he had examined it.

Mr. Cross, in reply, said that with regard to the Chairman's first question as to the bleaching action of ferric oxide, it was obviously due to a transference of oxygen to the fibre constituents, extending to the cellulose itself, and that amounted to disintegration, or as the bleacher called it "tendering." With regard to the complexity or simplicity of jute, he begged to refer the Chairman to papers in the Journal of the Chemical Society, 1880–1892. No doubt jute was an aggregate, but it was not complex in the ordinary sense of the term. It was not a mixture; it was an aggregate of bodies of varying molecular weights, but remarkably constant, and for all practical purposes it might be regarded as a homogeneous body. With regard to the Chairman's third question as to the general applicability of this process, what he had said was that the form in which the paper-makers would ultimately produce acetic acid would depend on local circumstances.

Mr. Watson Smith had asked about the cost of production. If they could get acetate of soda they could sell it for 16l. to 18l. per ton. The cost of producing it could be easily calculated by individual makers. It depended, of course, upon variable circumstances, upon the method of evaporation, and the price of coal, which might be 6s. or 16s. a ton. It was a question of circumstances; but taking into consideration the cost of evaporation and other matters, and the value of the product obtained, anyone would be enabled to arrive at something like the net return. With regard to sulphite liquors, Tollens had shown that these liquors were definite sulphonates containing the group OCH_3 . Of course anything like a distillation process was necessarily a complex matter; but the conditions were there for acetic acid being formed. It was a question for investigators; it was not for them to lay down any general *à priori* idea as to what might be got from destructive distillation of the mixture. With regard to the composition of the char, he had given a typical case. He had said that in the spent char a great deal of the soda remained in association with the carbonaceous residue. When that carbon was burned off they got pure ash, or carbonate of soda, and the percentage of anhydrous acetate in the char was 16, and of these 16, 15 were dissolved out by the lixiviating process.

SESSION 1892-93.

1893:—

Wednesday, January 11th.—Mr. Chas. A. Kohn, Ph.D., B.Sc., and Mr. A. F. Fryer, B.Sc. "The Cause of the Red Coloration of Phenol."

Meeting held Wednesday, December 7th, 1892.

MR. HENRY BRUNNER IN THE CHAIR.

CRITICAL NOTES ON THE CHEMICAL TECHNOLOGY OF INDIA-RUBBER.

BY HUBERT L. TERRY, F.I.C.

It is perhaps superfluous to say that the greater part of our imports of rubber, especially from South America and West Africa, come to Liverpool. No doubt the strange-looking lumps of material which come under more or less barbarous names to the auctioneer's hammer, are familiar to many business men. The natural history of this raw rubber does not materially concern the merchant but rather the manufacturer, though it must be confessed that it would not take the merchant long to learn all that the average manufacturer knows on the subject. To begin with, the question of future supply, it may be asked whether this is inexhaustible, or whether there is any danger of the raw material failing us. This may be answered by the statement that although 20 years ago there was a feeling akin to anxiety on this score the discovery in recent years that the basin of the Orinoco in Northern Brazil contains vast forests of unworked trees has served to dissipate this anxiety. The steps also taken by the Indian and Colonial officials in conjunction with Kew at home in interesting our Consuls and Colonial Governors in the matter have been, to some extent, instrumental in averting the threatened calamity. Forests of trees are no longer decimated, but are tapped in a methodical manner, and young trees are everywhere being planted. The acclimatisation of the *Hevea Brasiliensis*, of Para, is being carried out in East Africa, and notably in the Chardnar Forest in Upper India. Colonial-grown rubber does not as yet enter into competition in the open market with the ordinary product, yet samples of rubber from young trees have been received for examination. It struck me that there was a lack of tensile strength about a sample of Para grown in Mergui, and I shall await future samples with interest. It is important that where rubber trees are transplanted the climatic conditions should coincide as nearly as possible. Some doubt has been expressed as to whether the South American tree will ever come to maturity in Ceylon, where it has been planted. How are we to explain the difference between "island" and "up river" Para rubber, except as resulting from climatic

conditions. The same species of tree yields them both, but while the trees yielding the former grow on partially submerged land in the neighbourhood of Para, the latter is derived from trees growing on the hill sides of the Amazon tributaries. No doubt such instances might be multiplied in the case of other trees. Undertakings in forestry are not as a rule expected to yield any immediate return, but even if Colonial-grown rubber does not turn out the success anticipated, the matter is certainly of sufficient importance to warrant the attention it has received. Of course should any partial stoppage of supply occur through failure of trees, "trade corners" or otherwise, it would seriously cripple not only an important industry itself, but also the numerous trades—and are they not legion?—where rubber in some form or other finds application. It has been suggested that should the supply from South America fail, we have still the vast forests described by Stanley as existing in Central Africa to fall back upon. Anyone, however, proposing this must be set down as being lamentably deficient in knowledge of the subject, for there is very little rubber to be obtained in Africa that can compare at all with that from Brazil. That there are good and dry qualities obtained from Madagascar, Mozambique, and the Gambian coast I do not deny, but the majority of the African rubber, especially that from certain districts of the Congo basin, is sadly deficient in tensile strength, and contains impurities in the shape of resins and albumen which are almost entirely absent from the rubber of the Amazon and Orinoco basins. Why this should be, why the rubber milk of different species of trees should vary so much in its physical properties, when the hydrocarbon itself is always of similar composition, has not yet been explained, and the explanation is likely to be retarded owing to the difficulty of keeping the milk in its natural condition after its arrival in civilised parts. The following analyses of rubber-milk may be of interest.

I.

PRODUCT OF THE *Hevea brasiliensis*, PARA.

	Per Cent.
Caoutchouc.....	31.9
Resin.....	1.5
Albumen.....	0.5
Water.....	66.1
	100.0

II.

PRODUCT OF THE *Ficus Vogelii*, LAGOS COAST.

Mark.	Rubber per Cent.	Resin per Cent. on the Dried Rubber.	Yield of Rubber per Gallon of Milk.
			Lb. oz.
No. 1	30.0	31.5	2 13½
No. 2	28.5	32.1	2 11
No. 3	24.5	32.0	2 7½
No. 4	24.0	33.0	2 5
No. 5	21.0	31.0	2 0½

No. 1 milk had been sent in bottles from Para, having been previously mixed with some ammonia. It was liquid on arrival but soon coagulated when the bottle was opened.

No. 2 milk came to me through the Colonial Office two years ago, having been collected by the then Governor of Lagos, Sir Alfred Moloney, who wished for a report on the same. Altogether 15 ginger-beer bottles of this milk were received, representing five varieties of the *Ficus vogelii*, a tree growing extensively on the Lagos coast. Although nothing had been mixed with the milk to prevent coagulation it was liquid in all but three cases.

There was a considerable pressure of carbonic acid gas in the bottles, and the milk had a very acid reaction. It contained a small quantity of tannin, glucose, and albumen.

It should be mentioned in respect to the above figures, that the milk was collected at the wrong time of year and would therefore be under strength.

Owing to the large percentage and low melting point of the resins contained in this rubber, I could not but form an unfavourable opinion of it, and this was borne out by a practical trial in the works. Of course some uses might be found for it, but it certainly could not be looked upon as anything like a good quality, which the Colonial authorities had supposed it might be.

The question may be asked what is the probable value of the rubber forests discovered by Stanley. Are the trees the *Vakea* of Madagascar, the *Landolphia* of the Congo, or the *Ficus Vogelii* of the Lagos coast? If the latter the discovery is of little value. Putting aside, however, the actual worth of the rubber, the question of transport is really the crucial point. At present prices it would not pay to bring rubber thousands of miles before shipping it. All things considered, any great augmentation of our rubber supply from Central Africa need not be looked for in the immediate future. The concession of a licence to work rubber forests in West Africa on Government lands to Mr. Meiter of London claims some attention. Mr. Meiter is himself superintending the gathering of the rubber, which is a step in the right direction, as there is room for improvement in the whole system of rubber collecting and exporting in Africa. If the operations were more generally directed by men conversant with the modes and requirements of the manufacturers at home, the coagulation of the milk would no doubt be carried out in a better way than is usual. If the coagulated rubber also were sorted out into lots of equal elasticities it could be bought in Liverpool or London in a more satisfactory manner. Manufacturers know from experience that separate lots of rubber bought under the same name frequently turn out of anything but the same quality as regards strength after being washed and sheeted. How often do we see part of a washed sheet hanging in the drying-stove and part lying on the floor, showing that the sheet is made up of a substance of varying degrees of strength, or what comes to the same thing, of varying melting point. An object of special inquiry with respect to African rubbers is, how to coagulate the milk so as not to include the resins with the rubber. In a previous paper I have detailed the different percentages of resin found in various rubbers of commerce, and I showed that the quality of the rubber varied inversely as the percentage of resin. This statement must not, however, be taken as showing that African rubber if separated from its 20 per cent. of resins is equal to Para rubber. There are differences in the two products which cannot be explained away as being caused only by an excess of resin in the one case.

The question of the day then is, how can we so improve the inferior qualities of African rubber as to increase their market value? At the same time we must not lose sight of the fact that there is a considerable demand for rubber in cases where its elastic properties are but slightly brought into play, and therefore any treatment which increased the cost as well as improved the quality of low-class rubbers, would only meet with partial favour at the hands of manufacturers.

It cannot be said that the initial stages of the rubber manufacture owe much to chemistry, as it is the mechanical engineer who has had most to do. As an example of the perfecting of mechanism the wide fine sheet-cutting machine may be mentioned, whereby sheets of rubber are now cut 160 to an inch. The rôle of the chemist, it must be said, has been more in connection with trade disputes, and a good deal of the chemical work that has been done on rubber has been first brought to light in the Law Courts. The court has to decide whether the premature decay of a waterproof coat is to be put down to bad work on the part of the cloth manufacturer or the rubber manufacturer. Elaborate analyses are produced in court tending to show for one side that the cloth contains grease, oxide of copper, or other injurious matter, while the other side retorts that the rubber-proofing is a bad one and the cause of its own decay. The fact is these analyses are very little good. Under certain conditions, no doubt, a little grease or a few hundredths per cent. of oxide of copper may be injurious, but not necessarily in every case, and decay may

be brought about in goods by some irregularity in the manufacture quite undiscoverable by analysis. The investigation of these cases requires special experience, as there is extreme difficulty, when goods have gone bad, in fixing on which of the ingredients the blame rests.

In a paper read at the British Association Meeting, 1890, Mr. W. Thomson, in dealing with the action of oil on rubber, startled some manufacturers by the statement that the oily matters which were dissolved from oxidised or sulphurised oil by ether were not only not injurious to rubber, but in many cases were actually beneficial. The conclusion was thereupon arrived at by some manufacturers that the oil bogey had no foundation in fact. A little consideration, however, will show that the results obtained by Mr. Thomson are only what might be expected. In the oxidation, chlorination, or sulphuration, if I may use the term, of fatty oils it is extremely rare that any oil is unacted upon. The portion soluble in ether is then not free oil, but only a modification of the matter insoluble in ether, which indeed is clearly shown by its containing sulphur, chlorine, &c. Its action then on rubber would resemble that of glycerin rather than that of a fatty oil. This of course only refers to the sound oxidised oil. If this has undergone decomposition back again to its original state, or, at any rate, has altered its physical condition, then the matters soluble in ether would not be so harmless in their action.

In a more recent paper,* with which the name of Mr. F. Lewis is also associated, Mr. Thomson has detailed at some length his observations of the action of metals, acids, salts, &c., on rubber. He finds that chromium salts are not injurious, a fact which might seem somewhat superfluous to those of us who have been accustomed to use chromium regularly were it not that Mr. Tatlock had recently published a letter showing that chromium had a destructive action. It was hardly necessary to republish the action of acids on rubber, and although the inimical effect of small quantities of acid in rubber goods has, I feel sure, been exaggerated, it is not safe to judge, by the action of a bath of dilute acid on a sheet of rubber, what the action would be if acid were produced *in situ* in the goods. Mr. Thomson finds with some surprise that the action of hydrogen peroxide on rubber is nil. I think, however, that if he had tried an ethereal instead of an aqueous solution of this reagent he would have obtained a different result. Mr. T. Bolas, amongst others, has used this solution for years in rubber analyses.

With respect to the action of nitric acid on rubber I have gone into the matter at some length, and my experiments are yet in progress, a preliminary report only having been published.† The most dilute acid acts injuriously, but the action if allowed to proceed slowly results in the formation of a more or less nitrated body, and not merely of a resin. A yellow brittle powder obtained by the action of dilute HNO_3 on sheet rubber for six weeks gave the following figures on analysis:—

	Per Cent.	Calculated for $\text{C}_{10}\text{H}_{15}\text{NO}_2$
Carbon	50.50	66.29
Hydrogen	6.13	8.28
Oxygen	37.94	17.70
Nitrogen	5.43	7.73
	100.00	100.00

This body has explosive properties and is evidently a mixture of an oxidised and a nitrated substance. The practical bearing of these experiments is to show that nitric acid, even if very dilute, cannot be used in connection with rubber articles with impunity, and this fact should be borne in mind by chemists.

With regard to Mr. Thomson's experiments on textures it should be mentioned that the method of testing their

* Proc. Man. Lit. and Phil. Soc. 1891.

† Ibid.

life so to speak by exposing them to temperatures higher than they are intended to stand, cannot be considered a satisfactory one. Rubber is very susceptible to heat, and I have found that there is absolutely no connection between say, the hours that rubber will remain sound at 150° F., and the months or years it will remain so at 60° F. I own that this seems to be the only available method of testing if one does not wish to wait a year or two for results, but nevertheless I feel sure that it leads to erroneous conclusions.

The paper published by Gladstone and Hibbert, although of scientific interest, may be passed over as devoid of technical bearing. A paper by Heinzerling and Pahl (*Chem. Zeit.* 16, 15) gives details as to the compounding of chemicals with rubber and gutta-percha, but does not advance anything of great originality. Heinzerling also (*Chem. Zeit.* 16, 84) has summarised recent improvements in the manufacture, but this paper is mostly a compilation of patents.

A paper of some interest dealing with the analysis of complex rubber mixtures has just been published by R. Henriquez (*Chem. Zeit.* 16, 86, 87, 88), and may prove of interest to the analysts. He deals chiefly with the estimation of the different forms of "gummi ersatz" or "gomme factice" as it is variously called on the Continent. It is not my purpose on this occasion to discuss the matter of rubber analysis, but it should be borne in mind that by following out the plan of extracting rubber compounds with solvents as advised by the author, discrepancies are likely to arise if care is not taken to distinguish between organic matters such as resin, which are naturally a part of the rubber, and bodies of a similar nature which may have been added. The work is characterised by great attention to detail, more so, I think, than is required or which the ordinary analyst could find time for. Authors of papers on these and kindred technical analyses should not take it for granted that because no methods have been published they have not been worked out. I have no doubt that I am not alone in saying that there is little that is novel in Henriquez' paper. Analyses of manufactured articles should, in my opinion, always be performed by experts who, by the selling price, would know pretty well what to look for and whether a foreign body was to be classed as an adulterant or not. Chemists who have to read up should not attempt these analyses. A treatise, I may say the first of its kind, has just been published in Paris on rubber and gutta-percha.* The book, as a compendium of general information respecting the trade, is of great interest, especially in its botanical portion, which is very fully treated. The space in the book devoted to the manufacture of toys and small articles is an indication of the department where our neighbours do more than hold their own against ourselves. The figures for the export of sheet rubber to the Continent and our imports of German balls to be found in Board of Trade returns will emphasize this allusion. We have the engineering skill; they have the art of producing a nice-looking article out of poor materials. Perhaps technical education will put us right.

The promised work of Dr. Arlidge on Diseases of Occupations has appeared and gives an immense number of statistics relating to the hygiene of our trades. It is not to be expected that such a work written by one man could be free from errors—and, indeed, the author asks the reader's indulgence in the preface on this account—but if the descriptions of the industries generally are so vague as that of the vulcanisation of rubber, I am afraid the credit of the book will suffer. I am glad to see that beyond bisulphide of carbon he has little complaint against the rubber works. There are indeed some vague invectives against steam and sulphur vapour, but these seem to me to be put in as padding. I do not wish to deny anything said about bisulphide of carbon, but it should be said that the really serious cases where the brain has been affected have occurred, not in the ordinary vulcanising process as carried out in the larger works, but rather in small ill-ventilated workshops and in processes where dipping the goods into the liquid takes place. Hospital authorities in Paris, New

York, and Manchester, have had their say on the serious symptoms produced by this mephitic liquid and it is therefore with pleasure that I am able to announce that its use is being much restricted, inasmuch as it has found a rival in its chief application. Is it too much to hope that chemistry will find some harmless substitute for it in its remaining applications?

With respect to chloride of sulphur, though this is a very disagreeable substance to work with, I have never found it to undermine the health of the operatives. This is probably due to the fact that it is impossible to breathe much of it without following out a desire to remove from its neighbourhood. With naphtha vapour, the smarting of the eyes warns us when the fumes are getting too strong. I have never seen any one really overcome by naphtha because in the ordinary manufacture the vapour could not be inhaled strong enough. Sensational stories reach us sometimes from abroad of whole factories of workpeople getting light-headed, and though these statements may or may not be highly coloured, I suppose there is no doubt that strong naphtha vapour if inhaled does produce a species of intoxication something akin to that of opium.

It is not until the process of vulcanisation is reached that chemistry begins to play a part in the rubber manufacture. Here various reactions take place, all however, where steam or heat is employed being effected by the agency of sulphur. The action of sulphur on rubber is the principal one, while subsidiary actions leading to the formation of sulphuretted hydrogen, lead sulphide, &c., also take place. I am not aware that any paper has appeared settling the vexed question as to the nature of the vulcanisation process, and I do not propose to say anything myself on the matter on this occasion beyond a brief reference to the point of how much sulphur is really taken up and fixed. It is customary in books to state that 3 per cent. of sulphur is chemically combined and the rest mechanically held. It is supposed that the latter is soluble in caustic alkalis and the former not so. However, by repeated boiling I have brought the sulphur down to 0.6 per cent. without destroying its properties. Thus the figure usually given is too high.

A piece of sheet rubber immersed in a bath of melted sulphur for four hours at 135° C. was found not to be vulcanised. It then contained 3 per cent. of sulphur. After five hours' immersion it was quite vulcanised, being found then to contain 5.5 per cent. of sulphur. It may be shown in many ways that although only a very small amount of sulphur is really fixed by the rubber, yet it is impossible to get this amount fixed unless a considerable excess is present. Rubber will absorb free sulphur from its solution in alkaline polysulphides, but it is found impossible to get articles properly vulcanised in this way. Notwithstanding this, this process, known as Girard's, may be found religiously described in all text-books, ancient and modern. With respect to the action of sulphides on rubber it has been found in all cases that where these have been used as vulcanising agents their action has been due solely to the free sulphur they contain, generally in the amorphous condition. Owing to the formation heat of most of the metallic sulphides being above the melting point of sulphur, the sulphide of lead may be taken as the only one formed during ordinary vulcanising processes. This is rather to be regretted as the formation of sulphides is a means of fixing the excess of free sulphur which we have seen is essential.

Our Society had an interesting paper last session from Mr. Fawsitt respecting the dry heat vulcanisation of rubber by means of metallic iodides. The paper is in our Journal (this Journal, 1891, April 332-336), and I need not therefore abstract it for the purpose of reference. Without going into the important question as to its commercial success, a subject of interest to only a limited number of our members, I shall confine myself to the scientific importance of Mr. Fawsitt's paper. Unfortunately lack of time prevented him from working out the chemical action supposed to take place. Gladstone and Hibbert and I think some authority before them

* *Le Caoutchouc et la Gutta-percha* par E. Chapel, Paris, 1892.

† This has occurred in naphtha works.

have shown that iodine has no action on rubber in the sense of forming a definite compound with it, and people have therefore jumped to the conclusion that it is sulphur, which always accompanies Mr. Fawcitt's iodides, which after all brings about the reaction. As far as I have gone into the matter myself I think that some substitution of hydrogen by iodine certainly does take place, but not to anything like the same extent as in the cases of chlorine and bromine. Though the combinations of rubber with these latter, as shown by the specimens on the table, are solid stable bodies prepared directly, yet it is quite possible that some body may be formed by the action of heat on the iodide and rubber during the vulcanising process. The formation of hydriodic acid cannot be taken as proof that substitution of hydrogen in the rubber has taken place, because hydrogen would be liberated by the action of sulphur present. These are points, however, for Mr. Fawcitt to clear up.

The use of halogens in the vulcanisation of rubber is not a new idea, a patent having been granted in 1846 to A. Parkes for this purpose, though not for dry heat purposes. Chlorine and bromine, however, alone are too powerful in their action, and at the present time the only agent used on the large scale is chloride of sulphur. With regard to the action of this body, I think there can be no doubt that it is due to the chlorine, and that although some sulphur must necessarily be absorbed at the same time by the rubber, yet that this latter does not play any part in the reaction. Sulphur in the cold has no effect on rubber and chloride of sulphur must be looked upon as merely chlorine in a diluted form. The action of chlorine in whatever form applied may be measured by the amount of hydrochloric acid produced; in the case of chloride of sulphur, no doubt secondary reactions take place which do not occur in the case of chlorine alone.

The action of nitric acid on rubber has been already referred to. That of the gaseous oxides of nitrogen is somewhat similar. I have found that while the monoxide is without action and the dioxide has little action, the higher oxides act energetically. If a sheet of rubber be placed in a bottle containing air and higher oxides of nitrogen the yellow colour will soon disappear and the rubber be found to be surface-vulcanised to some extent. These vapours have been employed in practice for the vapour cure of rubber sheet but they cannot be said to show any advantage over chloride of sulphur, while a very little over-exposure destroys the rubber.

There seems to be some misconception as to the part which bisulphide of carbon plays in the cold cure process of vulcanising rubber goods, but there can be no doubt that it acts merely as a solvent and takes no part in the reaction. Substitutes for this liquid have been proposed 20 years ago, but none of these have been successful until quite recently, when the success which has attended the use of a product obtained from benzol refining, certainly warrants the assumption that the days of CS_2 are numbered for most of its former uses.

The problem of the devulcanisation of scrap and old rubber has been before the trade since vulcanisation was first practised, and cannot be said to have yet been solved. Of course rubber, especially of poor quality, has been "recovered" by the action of oil and heat, but it is not the original hydrocarbon reproduced. There being no doubt that during the process of vulcanisation with sulphur hydrogen is given off, it becomes necessary to return this hydrogen to the rubber. Mr. Lascelles Scott has proposed to do this by the zinc-copper couple, but I do not know whether he has any solid grounds for believing that this would be successful. The greater part of the sulphur in vulcanised rubber can be removed as H_2S by heating with petroleum oil of high density. In all cases of this sort, however, the rubber itself goes into semi-solution and it is doubtful if the very small amount of sulphur actually combined is removed. In one respect the recovery of rubber from vulcanised scrap resembles that of the recovery of tin from tinplate scrap and old plate. Where the waste is all pure rubber and when the iron is coated with pure tin the recovery process is of commercial importance. As, however, at the present time the greater part of the waste

which requires treatment is not pure rubber, and the majority of tin plates are not coated with pure tin, the aspect of the question is altered.

Although under the strict title of my paper I am precluded from extending my observations to gutta-percha, yet in the minds of most people, and I think of most chemists, the two substances are so closely associated that I shall close these notes with some references to a substance that can claim at any rate a chemical, if not a physical, kindred with rubber.

The future supply of gutta-percha is a subject of grave import at the present time, and it behoves our countrymen to be up and doing on the matter. The *Isanandra gutta* is not a tree to be found all round the equator. Its home is in the Malay Archipelago, though it seems likely that the historian of the future will have to use the past tense in this connection if rigorous measures are not enforced to prevent the wholesale destruction of the trees. Under the title of "Borneo caoutchouc," an interesting description of the gutta trees appeared in the abstracts of our Journal recently. This had reference to the work recently carried on by M. Serullas, descriptions of which have appeared in the Bulletin of the Société d'Encouragement. He is an advocate of the method of collection proposed by Jungfleisch. This briefly is to extract the gutta-percha from the leaves of the trees by boiling solvents instead of cutting down the tree and extracting the milk from the stem as is usually done. The tree is said to yield as much in this way as before, and, of course, it lives to afford a further yield. The process, however, strikes one as being more adapted to pharmaceutical preparations than to commercial products, and it should be remembered that a very similar process was proposed by L. Wray in 1886, which, on being tried by the Silvertown Company, was reported upon as unsatisfactory. As the composition of the chemicals used by M. Serullas have not yet been divulged, it is of course too soon to speak confidently as to the process.

Supposing that the supply of gutta did really fail, would its loss be severely felt by the principal users, the cable manufacturers? I think not; rubber, both pure and vulcanised, is replacing gutta more and more for electrical purposes. The triumphs of sythetic chemistry are not yet exhausted, and it should not be so difficult to obtain an artificial body with the required attributes. Again, though there seems no chance of the real gutta tree being found in the Brazilian forests or the African groves, yet there is evidence that trees of a somewhat similar nature exist, and small quantities of bodies closely resembling gutta and Balata have from time to time come into the hands of experts. The latter body, perhaps I should explain, resembles gutta-percha in that it contains a hydrocarbon of the same constitution associated with a large amount of a peculiar resin. It is the product of the *Mimucops Balata*, or bullet tree of South America, though it is probable that what comes into the English market is a mixture of the products of more than one species of tree.

Some discussion has recently occurred as to a scientific serial as to the amount of resins in sound gutta-percha. Now if the commercial product were all of one quality and from one species of tree, a definite percentage could be looked for. Generally speaking, any percentage from 30 to 55 may be found; the former from a soft, and the latter from a hard sample. Of course, unlike the case of rubber, the resins form a part of the gutta, and help to determine its peculiar properties; they must in no sense be looked upon as an impurity.

The following figures may be of interest as showing the fluctuations in the supply and price of gutta-percha as compared with rubber.

GUTTA-PERCHA.

	1887.	1891.
Imports..... Cwt.	24,115	69,611
Average price..... Per Lb.	s. d. 1 2	s. d. 2 2

CAOUTCHOUC.

	1887.	1891.
Imports..... Cwt.	235,337	278,837
Average price Per Lb.	s. d. 2 0	s. d. 2 1½

The increased figures for gutta-percha are, of course, due to the electric lighting movement, and had not the supply run short, the imports would have reached a much higher figure. The above prices derived from official statistics must not be taken as representing all the market changes; great fluctuations may occur in the price of South American rubber, which may not show themselves prominently in the annual statistics as calculated for the whole imports over the year.

Before concluding I should like to say one word regarding nomenclature. Caoutchouc is not a gum in any accepted chemical sense of the term, though I am afraid the terms "gum," "gomme," and "gummi" are too strongly established in American and continental usage to give way easily to more correct ones. It is difficult, however, to see on what system of classification they depend. To my mind caoutchouc is distinctly *sui generis*. This could be sharply subdivided into the two species of caoutchouc and gutta-percha, the distinguishing property of the latter being that it is softened by hot water. Any other means of distinction such as those founded on the behaviour of solvents, will be found to be due to accident rather than any specific property of these two bodies.

DISCUSSION.

Mr. BRUNNER said that Mr. Terry had given them an interesting paper, and he had no doubt there were many points upon which they would be glad to get further information. What Mr. Terry had told them had been new to him. Chemistry had not hitherto played any very large part in rubber and gutta-percha manufacture; but it seemed to him that the question of the recovery of old rubber was more or less a chemical problem. Then again there was a possibility of some of the supplies of gutta-percha running short, and of the price going up very much in the market, and that ought to stimulate chemists to try, if possible, to invent some substitute that might take the place of either one or other of these materials.

Professor CAMPBELL BROWN said that why chemistry had little to do with the manufacture was because the chemist did not know anything about india-rubber. He should first find out what india-rubber and gutta-percha were, and what position they held in the system of classification of carbon compounds; this knowledge would aid him to understand better their real properties and their behaviour with other chemical substances. He would like also to know what was the nature of the process called coagulation. Was it an oxidation process, or merely a molecular change?

Dr. KOHN said that several questions occurred to him during the reading of the paper, the answers to which might be of interest to others. In the early part of the paper Mr. Terry had told them that the quality of the rubber was in proportion to the amount of resin present, and he would like to know what information was to be had in regard to the nature of those resins. Another point was the action of chromium salts on the rubber. They were told that they had no injurious action, and it would be interesting to know whether the action was beneficial or neutral. Chromium salts in the presence of organic matter were known to undergo change themselves on exposure to light, and in addition to affect the organic matter with which they were in contact. In regard to the nitro-compound which Mr. Terry had passed round and which he told them was a mixture of an oxidation product and a nitro-compound he would like to point out that the explosibility of the compound might be due to its being an ester of nitric acid rather than a nitro-body. He did not quite follow why the formula

$C_{10}H_{15}NO_2$ was assigned to that nitro-compound, was it the result of analysis? Another point was the inefficiency of a two days' test for rubber, and the efficiency of a four years' test, in order to make out the quality of rubber. It brought out the necessity for much more inquiry into the chemical nature of rubber, and especially into the conditions under which certain reagents affected rubber. By finding out the active substances in the destruction of rubber, it would surely be possible to make this test both more rapid and more effective. He would also like to ask what gutta-percha was used for beyond making cables for electric light, and whether it could be employed instead of india-rubber for any of the purposes for which the latter was used?

Dr. RAWSON asked whether Mr. Terry would kindly again mention the name of the liquid used instead of carbon disulphide as a solvent for sulphur. He was rather surprised to learn that chromium salts were not injurious to rubber, for in their action on gelatin was very marked, as evidenced by the rapid strides which the chromium process of tanning was making. It would also be of interest to learn what was the difference between india-rubber and gutta-percha, other than that they were the expressed juices of different trees, say in their chemical composition, behaviour with reagents or from a physical standpoint.

Mr. TERRY, in replying to Prof. Campbell Brown, said that there was no chemical action involved in the coagulation of the rubber milk. The action was similar to that of separating the casein from milk by an acid. In Africa solutions of vegetable acids were much used for that purpose. In reply to the various points raised by Dr. Kohn and Dr. Rawson, he said that there was very little information to be got about the resins occurring in the various rubbers of commerce, but he would refer Dr. Kohn to a paper by himself (the speaker) in the Journal for 1889. Surprise had been expressed that the action of chromium salts on rubber was not injurious. Whatever the ease was with leather he could only repeat that nothing had been proved against chromium in the case of rubber, even the red chromic acid having no action. Chromium salts were not used in the manufacture and it was in the case of mordanting cloth for textures that a question as to their action had arisen. The uses and manufacture of rubber and gutta-percha were quite distinct, and although for certain purposes mixtures of the two might be used to a small extent yet the great bulk of the latter was used in the insulation of cables.

In regard to the substitute for carbon bisulphide in the cold cure vulcanizing process he was precluded from saying anything very definite as to its composition, but it was a hydrocarbon of the aromatic series. It was not so volatile as carbon bisulphide and this precluded its general use, but at the same time its use had put an end to the fires which so often occurred with carbon bisulphide.

Dr. Kohn had referred to the question of testing by heat. What he had meant to express in the paper was that there was no royal road to the rapid testing of rubber goods for the uninitiated to follow. In some cases, notably in the heat tests as adopted by the Admiralty, information could be gained in a few hours as to whether mechanical goods were up to a certain standard. But this did not apply to cases where the goods had been manufactured in the cold and were intended to be used at ordinary temperatures. Light was the chief factor that determined the life of rubber; a piece of elastic thread which would keep sound for many years in a dark cellar would go rotten in as many months if exposed to sunlight.

SESSION 1892.

Meeting held Friday, 2nd December 1892.

DR. E. SCHUNCK, F.R.S., IN THE CHAIR.

ON COP-DYEING.

BY CARL OTTO WEBER, PH.D., F.R.S.

FOR a number of years experiments on a more or less extensive scale have been carried on, with a view to accomplish the dyeing of textile fibre, especially cotton, at the most advantageous stage of their manufacture into yarns. The efforts, more or less successful, to dye cotton and wool in the raw or loose state, to dye the sliver, rovings, carded or combed wool, and cotton and wool in the cop, are all exertions in the same direction. At first sight it might appear that the simplest and most rational solution of this task would be the dyeing of the fibres at the earliest stage of their manufacture, *i.e.*, in the form of loose cotton or wool, but this is not so for various reasons. In the first instance all the colours requiring long-continued boiling cause the loose fibres to become in the process of dyeing entangled to such a degree as to cause very considerable loss in spinning, far in excess of the losses incurred when the undyed fibre is spun, reeled into hanks, dyed and wound back again into pirns, ready for the shuttle. Fibres dyed in the loose state are moreover generally very much harsher and stiffer than the natural fibres and therefore give infinitely more trouble in spinning than the latter, and to these drawbacks must be added the fact that the spinning, particularly of dark grey, brown, blue and black shades is an operation which proves exceedingly trying to the eyes of the operatives and very naturally decreases the production in proportion. There are even cases on record where the operatives refused to work on that account. But even supposing that all these difficulties could be overcome the fact would still remain that of the hundreds of different shades required for weaving only a very few are used in such quantities as would allow a spinner to keep his plant regularly employed, who could not afford to execute orders of a few hundredweights of fancy shades, owing to the loss of time incurred through frequent cleaning of a number of machines for each new colour. Difficulties of a similar nature arise whenever we attempt to dye the fibre at one of its manufacturing stages previous to that when it is obtained in the shape of cops, so that we come to the conclusion that generally speaking the dyeing of the textile fibres cannot advantageously be proceeded with before the actual conclusion of the spinning operations. This shows clearly the importance and advantage of cop-dyeing as against the dyeing of the raw or partly-manufactured fibre on the one side and hank dyeing on the other side. The fact that

large quantities of cotton are dyed in the raw or partly-manufactured state does not in the least affect these conclusions, as this is done for the purpose of spinning mixed yarns or colours as in the manufacture of vigogne.

In this case the dyeing of raw or partly-manufactured cotton being the only way to produce the desired effect, we are compelled to put up with whatever drawbacks the process may possess. From this it is further evident that cop-dyeing by no manner of means enters into competition with the rightful dyeing of unspun or half-spun cotton, although yarn and warp dyeing is bound to be considerably affected by it; and it is further likely that the production and dyeing of half-woollen goods will also more or less be influenced, although it may be difficult to judge the probable extent of this influence at the present time considering the splendid results obtained by Messrs. Cassella & Co., with their diamine colours in the dyeing of half-woollen goods.

The great importance of cop-dyeing is generally admitted at the present time, so that I need not say any more in this respect. But quite as well known is the great difficulty of this kind of dyeing, especially if it be desired to apply all the colouring matters and dyeing methods which are at present used in hank dyeing. There is a number of different cop-dyeing machines now being experimented upon, and the results achieved by the various inventors are watched with the keenest interest. The time has not arrived to award the prize in this competition to any one of these machines; but there is at the same time no doubt that the principles which have to be observed in the construction of a cop-dyeing machine of general applicability are already fairly established. Similarly the characteristic methods and operations by which cops can be dyed in these machines are developed to such an extent already that a fairly complete record of both of them may be said to be of general interest, and I believe that an exhaustive description of the present state of this new and most important dyeing industry will be welcomed by many who take an interest in this new departure in dyeing. I may say that I am in no shape or form interested in the eventual triumph of either of the various machines over the others, but what information I am able to convey to you on the subject is derived from actual experience and practical working. I can, however, not refrain from giving you my well-considered opinion that as matters stand at present British enterprise seems likely to carry off the prize in this fierce struggle for supremacy in a new and important industry; the results of the severest tests, and of continuous practical working on the machine of two English inventors being far ahead of anything achieved either at home or abroad.

I.—THE MECHANICAL PRINCIPLES OF COP-DYEING MACHINES.

In examining the mechanical or engineering side of the question of dyeing cops, we find ourselves at once confronted by three points of fundamental importance:—

1. Perfect evenness of the dye throughout each cop.
2. Perfect evenness of shade in and between the different lots dyed.

To these must be added a point of specifically economical bearing:—

3. Time required for each dyeing operation, *i.e.*, working capacity.

We can safely say that the machine answering the above requirements by means of the simplest mechanical appliances, will be the best. Of the above points, 1 and 3 depend entirely upon the construction of the machine, while point 2 is as much a question of mechanism as of dyeing methods.

If we immerse a cop in cold water, the latter slowly penetrates into the former, but the complete impregnation of the cop by the water is a matter of many hours, and even days with the very fine counts. The rate at which the water penetrates into the cop can easily be observed by adding to the water some dye, which on cutting an immersed cop parallel or in a right angle to the core, at once shows how far the water penetrated in a given time. In the first

instance this difficulty of impregnating is caused by the particular build of the cop which renders it very difficult for the occluded air to escape and make room for the water to get inside, but a great obstacle is also to be found in the vegetable, oily and resinous impurities contained in the grey cops. If we immerse the cops in hot water we observe in the first instance, that the air escapes much more rapidly owing to its expansion by the heat of the water, at the same time a considerable quantity of the impurities of the cops becomes dissolved or emulsified, and consequently the water penetrates much more rapidly. But even under these favourable conditions, in using a hot solution of some suitable dye the cop could not be dyed in a satisfactory manner, as it would become much darker on the outside than inside, chiefly owing to the fact, that although the hot dye-liquor has expelled the air from between the threads of the cops, there remains still the air which fills the central channel of each cotton fibre, and the complete expulsion of which requires either long-continued boiling or treatment in vacuo, also preferably at higher temperatures. This leads to the formulation of the first important principle required in a cop-dyeing machine:—

I. Perfect displacement of the air from the inside and outside of the cotton fibre is an essential requirement of the thorough penetration and saturation of the cops by the dye-liquor, and is best obtained by treating the cops with the dye-liquor in vacuo.

We shall see later on, that in many cases the non-observance or misunderstanding of this important principle led the inventors to substitute pressure for the vacuum. All machines of this description are wrong from the start, and if they did not turn out a downright failure, they are of very limited applicability only, and are generally conspicuous by the great amount of waste they produce in working. It is evident, however, that in complying with principle I., we obtain practically only the complete impregnation of the cops with the dye-bath, and under these circumstances the cotton would simply take up the dye contained in the absorbed quantity of bath, after which the cops would merely contain more or less colourless water. Taking into consideration the usual concentration of dye-baths, which very rarely exceeds 0.5 per cent. of colouring matter, it is evident that mere impregnation of the cops with such baths could not produce dark shades; and moreover, the outside of the cops being much longer in contact with the dye-liquor, would be much darker dyed than the inside. To overcome this difficulty we have to adopt another means which therefore forms the next important principle of cop-dyeing machines, namely:—

II. In order to obtain perfect evenness of dyeing throughout the cops, it is necessary for the dye-bath to circulate freely through the cops, so that at any time the concentration of the dye-bath is the same at every depth of its penetration into the cops.

This point is of very great importance in a cop-dyeing machine, as a slow circulation at a low hydrostatic pressure will allow the concentration of the dye-bath to vary in different parts of the cops. Likewise the quantities of dye-liquor passing through various parts of the cops will differ very widely, especially if the cops contain hard and soft places. In both these cases the result will be that the cops are unevenly dyed.

The principles I. and II. contain everything required to fulfil the first of our conditions, namely, to dye the cops perfectly even, and any machine carefully designed on these two principles will be satisfactory in that respect. Our second condition demands perfect evenness of shade in and between the different lots dyed, or in other words the maintenance of the standard shade for any number of cops dyed in successive operations. The observation of our two first principles does not ensure this, although they contribute very largely to the possibility of achieving this feat. I have stated above that our condition No. II., is as much a point of the mechanical principles upon which a cop-dyeing machine has been constructed, as of the methods of dyeing employed with the machine, and we shall now have to examine how far this second condition is dependent upon the construction of the machine. The part the dyeing methods

play in this respect will be discussed in the third part of this paper.

In dyeing yarns in the hank in the ordinary dyeing beck, the uniformity of the dyed shades in different lots is regulated by the concentration of the dye-bath, the temperature, and the time of the immersion. As far as cotton-dyeing is concerned the volume of dye-bath used is of comparatively little influence, as with mordant-dyeing colours the maximum quantity of dye is stoichiometrically fixed by the quantity of mordant previously fastened upon the fibre, while with the substantive dyes the obtainable depth of shade is entirely a question of concentration, temperature, and time. These three factors are, of course, of the same importance in cop-dyeing as in every other branch of dyeing. The maintenance of the original concentration of the dye-bath requires to be considered in the construction of cop-dyeing machines only in so far as every precaution ought to be taken to prevent any alteration of the concentration of the dye-bath from other causes than that of the actual dyeing itself. For this reason it must be considered a great mistake to heat the dye-bath with direct steam, as the dilution of the bath in this manner is exceedingly difficult and troublesome to compensate for and consequently makes it almost impossible to maintain the standard of shade. This difficulty can generally be avoided by heating with indirect steam through coils. Of course the concentration of the dye-bath can also be altered in an opposite manner, *i.e.*, through evaporation, but provided the temperature of the dyeing-bath always to be kept at the same point, the evaporated quantities of water for equal intervals of time will remain constant, and it is certainly much easier to dilute the baths than to restore again the higher concentration of diluted bath, especially if the degree of dilution attained from time to time is such a very variable quantity as in the case we have been considering. As regards the immersion of the cops in the machine, this can be either performed by a continuous or intermittent process. In the first case the dye-bath circulates through the cops during the whole time of the dyeing operation, and the machine ought to be so constructed that the operation can be interrupted at any moment. In the second case, working with intermittent immersion, it is essential that every immersion should require the same time. In both cases, whether the immersion be continuous or intermittent, is it desirable that during each immersion of the same duration equal volumes of the dye-bath should circulate through equal weights of the cops. This requirement may not be of such eminent importance in the dyeing of cotton cops, although it undoubtedly very materially assists in the important task of obtaining all consecutive lots of standard shade. But so soon as woollen cops have to be dyed this requirement is of paramount importance. From the above we deduce the two further principles:—

III. The dye-bath must not be subject to dilution through direct steam.

IV. The immersion of the cops can be either continuous or intermittent. The immersions must be of equal duration, and the volume of liquor circulating through equal weights of cops must be the same for each immersion.

The time required for each immersion is a point of very great interest as it is a very important factor in determining the working capacity of a cop-dyeing machine. All the more so as the large majority of these machines operate with comparatively very small quantities of cops at a time. There is, up to the present, only one cop-dyeing machine in which large quantities of cops are treated in each operation, but it appears that the results obtained are far from satisfactory with regard to quality. The difficulty of obtaining perfect circulation of the dye bath through the cops increases very considerably with the quantity of cops dyed in each operation, and in proportion, of course, increases the difficulty of dyeing the cops even. This observation seems to have been made by every individual designer or inventor of cop-dyeing apparatus, as, with one exception, all operate with very small weights of cops at a time. With regard to the possible output of a cop-dyeing machine everything depends therefore upon the time required for each dyeing operation, and this, of course,

varies with the different classes of dyes employed. Generally speaking we know that the process of dyeing with the substantive dyes is finished as soon as the intercellular cavities of the cotton fibre appear to be filled with the colouring matter, and it is evident that the first principle we established with regard to cop-dyeing machines, demanding the expulsion of the air from the cotton fibre, will reduce to a minimum the time required for this dyeing process, which, in dyeing in the open beck, requires about 30 minutes. In dyeing mordant colours the question of time required is chiefly a question of how long it takes to produce upon the fibre the chemical compound of dye and mordant, *i.e.*, the colour-lake. But these points belong already to the matter of cop-dyeing proper, and will be discussed later on. In certain publications attempts have been made to compare the merits of the different systems by giving the quantities of cops which can be dyed in a working day in the various machines. At the present stage of cop-dyeing machines and cop-dyeing anything more misleading can scarcely be imagined. Cop-dyeing at the present day is eminently a question of quality and not of quantity. It is to-day a matter of absolute indifference whether a machine will dye 500 or 5,000 pounds of cops; the only question of actual importance is whether the machine will dye any quantity of cops dyed in succession perfectly even and without injuring the build of the cop. The machine that will do this, and, at the same time, can be applied to all the various dyeing processes is a perfect machine.

There remains only one more point to be mentioned with regard to the construction of cop-dyeing machines, but one the importance of which cannot be exaggerated. The cops possess a certain build or structure, which is the result of the particular mechanical winding action of the mule, and upon this build or structure, its mathematical regularity, depends to a great extent the behaviour of the cops in the loom. Every alteration in this normal build of the cops is at once noticeable in the weaving, by the frequent breaking of the thread, and the unwinding of the yarn in coils. This makes it evident that all cop-dyeing machines ought to be so constructed as to prevent any deleterious mechanical interference with the normal build of the cops. Thus we obtain as last principle:

V. *The unavoidable mechanical influence upon the cops by the circulation of the dye-baths through them ought to be of such a nature as to preclude any alterations in the shape or structure of the cops.*

The mechanical action to which the cops are subject while being dyed is that of the forced circulation of the various baths employed through them, so that with regard to principle V it is important to decide which mechanical influences, incidental to forced circulation, are liable to injure the cop. In Fig. 1 I give the section of a cop.

Fig. 1.

In causing the liquor in a cop-dyeing machine to circulate through the cops in the manner indicated by the arrows, it is obvious that the resistance offered by them to the passage of the liquors will cause the cops to bend or bulge in the manner indicated by the dotted lines. Such one-sided pressure will have a most deleterious action upon the build of the cops. The only rational way to avoid this one-sided pressure is to arrange the circulation in such a manner that the circulation radiates in a right angle to the core of the cops either to or from the centre of the cops (Fig. 2). The cop then suffers a slight compression, or expansion respectively, but no disturbance in the build is caused thereby, owing to a compression or expansion in one direction being exactly counterbalanced through an exactly similar action in the opposite direction.

Fig. 2.

II.—THE COP-DYEING MACHINES OF THE PRESENT.

It might be interesting to critically examine some of the most important cop-dyeing machines from the point of view of the principles we have just laid down. In doing this we shall, perhaps, not arrive at a certain conclusion as to which of the cop-dyeing machines of the present is the best, but there will not be much difficulty in finding out which of those machines answer all the requirements contained in our four principles. I am fully aware, that in attempting in this manner a sort of criticism of the existing cop-dyeing machines, I am undertaking a not altogether pleasant task, as on the face of it there is no doubt whatever that only a small minority of these machines will survive the experimental stage; the rest are doomed to oblivion. Considering

Fig. 3.

that cop-dyeing is as yet surrounded by a halo of deep mystery, chiefly for reasons best known to the cop-dyers themselves, an impartial discussion of the features, merits, and failings of the various cop-dyeing machines can in the end only serve to promote the cause of cop-dyeing.

I propose to discuss the various machines in the order in which application for letters patent has been made for them. Obermaier's machine heads the list. The construction of this machine (Eng. Pat. 2181, April 30, 1883) is shown in Fig. 3. The space M between the two perforated cylindrical vessels B and C is uniformly and densely packed with the material to be dyed, any hollow spaces caused by the irregular shape of the cops or bobbins are filled with loose textile material.

In order to keep these materials in their position, the piston cover E is screwed down upon them. By means of the rotary pump G the dye-bath is then forced into the cylinder C from where it penetrates through the textile material contained in space M, and subsequently flows through the perforations of the vessel B in the collecting vessel A, from where it again enters into circulation.

From this short description of the working of Obermaier's machine, we learn in the first instance, that the impregnation of the textile material is not performed in *vacuo*, but simply by means of a force pump. The perfect displacement of the air, especially of that part of it contained in the cotton fibre itself, will therefore occupy considerably more time, than if working in *vacuo* had been preferred. This disadvantage is of course much more noticeable in working with cold baths than it is with hot baths. It is probable therefore that the mordanting of textile materials in this machine, with cold baths (alumina, chrome, and iron mordants) will offer very considerable difficulties as regards thoroughness and evenness of impregnation. The possibility of the perfect impregnation of the textile material will also depend very essentially upon the care with which the machine has been charged, otherwise principle II. cannot be complied with, and the circulation will differ in intensity in various parts and sections, rendering thus the observation of principle IV. impossible. The observation of our principle III. offers no difficulty in this machine. The fact however that in this machine the cops to be dyed are subjected to not inconsiderable lateral mechanical pressure through the piston cover E is a very serious drawback. The great sensitiveness of cops against lateral or axial pressure, makes it almost impossible to guard the cops in this machine against detrimental or structural alterations, this all the more so, as after the dyeing operation, the vessel B C containing the cops is hydro-extracted on a centrifugal machine, in order to get rid of the superfluous dye-liquor retained by the textile material, which in this process will be pressed towards the outer wall of the vessel. I have no doubt that, in the dyeing of loose and partly manufactured fibres

and yarns in the hank, Obermaier's machine gives very good results, but for cop-dyeing it is, to say the least, of minor importance only.

Graemiger's machine (Eng. Pat. 11,497, August 23, 1887) has been constructed as a cop-dyeing machine essentially. The cops are put upon hollow perforated skewers which are then fixed upon the perforations of a conical or cylindrical drum (Fig. 4) which revolves air-tight round a similarly

Fig. 4.

shaped receptacle. The latter is divided into chambers which are connected respectively with a pump and an exhaustor, the former in the first phase of the revolution drawing the dye-bath through the cops, the latter in the second phase of the revolution drawing air through the cops, in order to remove the excess of dye-liquor. The impregnation of the cop

Fig. 5.

with the dye-liquor and the circulation of the latter through the cops, is performed in this machine by means of the above-mentioned pump, which here has upon the cops the same effect as a slight vacuum, and as far as this is concerned, the machine ought to work very well.

Unfortunately it possesses a very weak point, which consists in those two concentrically arranged drums of which the outer one is supposed to turn air-tight upon the inner one. As long as the gliding surfaces of these two drums have not suffered from corrosion, their air- and liquor-tight fit can easily be ensured and the machine will work satisfactorily; but as soon as through the unavoidable friction these drums and chambers lose their air-tight fit the working of the machine necessarily becomes deficient. This corrosion very quickly becomes noticeable, especially if mordant baths be employed. Hot baths of tannic acid, baths of acetate and sulphate of alumina and alkaline solutions of alumina and chromium peroxide, and in a lesser degree, all dye-baths are sure to cause this corrosion, and the progress of this corrosion is greatly assisted by the friction between the working parts. The circulation of the dye-liquor under these circumstances is bound to become deficient and irregular, and the contamination of the baths by the products of the corrosion must also have a very deleterious influence upon many of the shades dyed. In a later patent (Graemiger, Whitehead, Mason and Leigh) this drawback has been somewhat minimised by a reduction of the total area of the gliding surfaces, but it still forms a very weak part of this machine, upon the construction of which a very great amount of ingenuity and skill has been brought to bear. If the inventors should not succeed in remedying the above fault radically, there is very little prospect of this machine ever becoming of any importance.

Mason and Whitehead's cop-dyeing machine (Eng. Pat. 14,019, Sept. 29, 1888) consists of the dye bath *c* (Fig. 5) placed under the rectangular frame *w*, which carries the cylinder *c*, which is connected with the pump *f*, and the vacuum cylinder *h*. On the lower end of this cylinder a stuffing box *b*₂ is arranged in which the tube *a*₁ moves vertically. The lower end of this tube carries the cop plate *a*, which consists of the chamber *a'* and the plate *a*. The latter is perforated and in the holes are placed the cops which have been put on hollow perforated skewers. By means of the cops *a*₂ the cop plate may be immersed into the dye-bath *c*, or be withdrawn from it. If the cop plate has been immersed in the bath, the former is connected with the pump *a*₃ by opening the valve *p*. The dye-liquor then circulates through the cops, passes into the chamber *a*₁, rises into the tube *a*₃, and travels through *c* and *d* to the pump *f*, from where it returns to the dye-bath through the pipe *e*. If the cops are dyed the cop plate is raised above the surface of the dye-bath, valve *p* is closed, and valve *s* opened, thus connecting the cop plate with the vacuum cylinder *h*, whereby the superfluous dye-liquor is removed from the cops. In order to expel the air from the cops previous to their impregnation with the dye-bath, a hood with valves, through which afterwards the dye-liquor is admitted, can be placed over the cop plate. From this description we see that the apparatus is fairly well in accordance with all our principles, but, at the same time, it must be said that the construction of the machine is exceedingly clumsy and a very cumbersome appliance for practical working.

One of the most interesting cop-dyeing machines of the present as regards its manner of working, is Mommer's machine (Eng. Pat. 2763, Feb. 20, 1890). This machine is not constructed upon principles which would be applicable to the treatment of individual cops, as is the case with all those machines working with the cops fixed in hollow perforated skewers. In this machine, which is in this respect identical with Obermaier's, an attempt has been made to form as it were a solid block of cops offering in all its parts the same resistance to the dye-liquor penetrating into and circulating through it. The machine (Fig. 6) consists of the dye-vat *A*, the box *a* in which the "cop block" *b* is inserted and the pump *E*. These three parts are connected with each other by means of the pipes *B*, *B'*, *D*, *D'*, and *F*. The circulation of the dye-liquor through these pipes and subsequently through the cops can be reversed by means of the valves *C*, *C'*. The

cops are put on solid skewers and then inserted into rectangular wooden frames in the manner shown in Fig. 7, each

Fig. 7.

frame thus forming a screen or diaphragm of cops. A number of these frames are inserted face to face into the box *a*. It will be noticed that the circulation of the dye-liquor through such a cop block proceeds in the horizontal line, penetrating all cops from one side and passing through them in a right angle to their cores, while in all other systems, except Obermaier's, the circulation radiates to or from the core of the cops. Mommer's machine is therefore the only one working with solid skewers, all other machines, as long as they employ any skewers at all, use them hollow and perforated.

This machine does not work with a vacuum as our principle I. demands, but this in itself will not prevent the perfect impregnation of the cops, although it will make the process rather a slow one. There is no doubt, however, that the circulation of the dye-bath (principle II.) through the cops in Mommer's machine is very unsatisfactory. It is unquestionable that the dye-bath will penetrate the cop block in the machine, but it is utterly impossible for the amount of circulation to be the same in every part of the block. This being admitted, it necessarily follows that many of the cops will be unevenly dyed. Such an irregular circulation will be caused in Mommer's machine by the solid skewers upon which the cops are fixed, and the effect of which upon the circulation will be readily understood by anyone acquainted with the laws regulating the forced circulation of liquids through cops. In Fig. 7 is shown a diagram illustrating the circulation of the dye-bath through the cops in Mommer's machine. In the diagram *a x b y* is the section of a cop, *c* the corresponding section of the solid skewer.

The circulation of the dyebath through the cop is supposed to proceed in the direction indicated by the arrow, *i.e.* from the left to the right. The zones $a a^1 a^2$ and $b b^1 b^2$ then

Fig. 8.

indicate those parts of the cop in which the circulation proceeds under normal conditions. In the zone $x c$ the circulation proceeds much slower owing to the diversion of the liquid on the skewer and for the same reason no circulation whatever is possible in the zone $y c$ and the impregnation of this part of the cop is merely due to capillary action. Prompted, perhaps, by a knowledge of this fact the inventor of this machine provided for the reversion of the circulation. But, as will be easily seen, this reversion will only have the effect of eliminating the difference between zones $x c$ and $y c$, but will only increase the difference between zone $x c y$ on the one hand and zones $a a^1 a^2$ and $b b^1 b^2$ on the other hand. It is probable that as long as only light shades are dyed these differences are rather insignificant, but in the dyeing of medium and dark shades unevenness is sure to result. Also the fact that in this machine the dye-liquors are forced through a number of cop diaphragms of very considerable depth or thickness does not very well agree with our principle II., as to the high importance of which scarcely any doubt can exist. I mentioned before that of all the mechanical actions deleterious to the build of the cops, none is more dangerous than lateral unbalanced pressure, and considering that in Mommer's machine the cops are during the whole of the time exposed to very considerable pressure from one side only at a time, this looks

anything but hopeful with regard to principle V. The above mentioned difficulties and doubts are probably least noticeable when dyeing with the substantive dyes, but they will certainly almost entirely prevent the dyeing of mordant colours in this machine.

Surprising simplicity is the most striking feature of Crippin and Young's machine (Eng. Pat. 1157, Jan. 22, 1890), which consists mainly of the dye-vat a , the cop chamber b and the receivers b and f (Fig. 8). The cops are put on hollow perforated skewers, which are then inserted into corresponding holes in the cop plate. The cop plate is then transferred into the cop chamber. The latter by means of pipes is connected with the vacuum cylinders or receivers b and f , and by simply pushing a lever acting upon a steam jet exhauster, a vacuum is created in b , drawing the dye liquor from vat a into the cop chamber, through the cops and into receiver b . Pulling the lever back into its normal position at once interrupts the circulation, and the dye-liquor returns from the receiver b automatically into the vat. Another movement of the lever produces the vacuum in f which now extracts from the cops all the superfluous dye liquor, which is subsequently also again discharged into the bath. The waste steam from the exhauster passes through a coil in the vat a , heating the dye liquor. By an improvement in this arrangement (Eng. Pat. 4928, March 19, 1891) it is possible to let the dye bath circulate from the outside to the inside of the cops or *vice versa*.

With regard to the construction of this machine it will be noticed that it contains no moving parts whatever and especially none that would move in contact with the dye-liquor. The importance of this advantage, as compared with the arrangements in Graemiger's, Mason's, and Whitehead's and Mommer's machine cannot be overrated. By this total absence of moving parts the wear and tear of the machine, and consequently repairs of it are reduced to insignificance. The machine further allows a continuous control of the actual amount of circulation of dye-liquor through the cops, which in a high degree assists in obtaining identical shades in consecutive operations. The machine works with a vacuum of from 12 to 15 pounds, and it will be easily understood, that this will induce a most energetic circulation, which as a matter of fact amounts to nearly a gallon of dye-liquor per cop, and per

Fig. 9.

Fig. 10.

minute. In the presence of such an energetic circulation the existence of hard and soft places in the cops is no longer able to exert any influence upon the evenness of dyeing, so that this difficulty has no practical existence in this machine. The capacity of this machine with regard to the output of dyed cops is considerably less than in Obermaier's and Mommer's machines, and about the same as in Graeniger's machine, but in its rational construction, universal applicability to all dyeing processes, safety and simplicity of working, Crippin and Young's machine stands far ahead of all others.

In A. and M. Koblenzer's machine (Ger. Pat. 55,787, March 26, 1890) the cops are fixed upon a sort of filter-plates *bb* which are then placed in the chamber or cylinder *a* (Fig. 10). The cops are then first treated with steam, by means of the perforated steam coil *d* and subsequently the dye-bath contained in the reservoir *e* is forced into the cylinder *a* by means of steam pressure. The cops are thus simultaneously treated with a current of steam from below and the spray of dye-liquor from above, the dye-liquor gradually running to all the filter-plates carrying the cops. Any excess of dye-liquor eventually leaves the cylinder through the pipe *K*. It is certainly not easy to understand this peculiar dyeing process, and the manner in which anything like an efficient circulation of the dye-liquor through the cops is obtained. Neither of our principles bearing on this point is applicable to the machine, and if it is at all possible to dye cops satisfactorily in this machine, it is certain that this can only be achieved with the substantive dyes. To dye basic or acid mordant dyes, indigo or aniline black in this machine is an utter impossibility. I have seen a number of cops dyed in this machine with substantive dyes, but the surprising softness of these cops, although perhaps accounting for the evenness of the dye throughout the cops, is not very promising with regard to the result of the subsequent use of these cops in the loom.

P. Kornfeld's machine (Ger. Pat. 56,369, July 17, 1890) avoids the use of skewers altogether. Each cop is inserted in a tubular case *H* (Fig. 10), in which little projecting plates are provided in order to compel the dye-liquors to penetrate

Fig. 11.

into the cops. The apparatus may be useful for experiments on a laboratory scale, but is quite useless for practical cop-dyeing, owing not only to its output being infinitesimally small, but also to its management being troublesome in the extreme. A great deal of injury must be done to the cops by the projecting resistance plates. Herzfeld and Stommel's machine (D. P. A. 11,325) is very much like Kornfeld's machine, but those dangerous resistance plates are avoided. But the use of this machine on a large scale is quite as hopeless as that of Kornfeld's machine.

Although there is quite a number of other patents for cop-dyeing machines in existence, it would be needless to occupy space with their description, as they offer no essentially novel points for our consideration.

From the above we necessarily come to the conclusion that only very few of the numerous cop-dyeing machines have before them any prospect of success as soon as they are used to dye other than the substantive dyes. And it must not be forgotten that the substantive dyes answer the

actual purpose of cop-dyeing very badly, the great majority of them "bleeding" so excessively that in many cases cops dyed with these colours can not be used together with cotton, wool, or silk in the grey or bleached state, or dyed in light shades. Cop-dyeing will never become of any importance unless it is able to work with all the mordant dyeing colours, including the alizarin dyes, and also indigo and aniline black. But all these dyes are a very much severer test on the efficiency of a cop-dyeing machine than the substantive dyes.

I have remarked before that the question of the capability of production or the output of the various cop-dyeing machines is rather premature. It has been stated that in 10 hours Crippin and Young's machine will dye 25,000, Graeniger's 80,000, and Mommer's machine 360,000 pin-cops, but at the present stage of cop-dyeing this statement is useless for the purpose of weighing the intrinsic merits of one machine against those of the other, and can only serve to grossly deceive the uninitiated. Those figures are rendered still more valueless, owing to the cost of working of the different machines not being known; and in view of the almost absurd secrecy observed by the cop-dyers, there is little prospect of these data being obtainable in the near future.

III.—THE PRACTICE OF COP-DYEING.

The methods employed in the dyeing of cotton depend upon the chemical nature of the colours employed, and can accordingly be divided into three classes:—

- A. Direct dyeing (substantive) colouring matters;
- B. Mordant dyeing (adjective) colouring matters;
 - (a.) Acid dyes;
 - (b.) Basic dyes;
- C. Pigment colours.

A.—Direct Dyeing (Substantive) Colouring Matters.

The application of the direct dyeing benzidine and diamine dyes in cotton-dyeing is so very simple that these products appear particularly well suited to cop-dyeing. As all these dyes are dyed in one bath there is also one machine only required to dye them on cops, while all other dyes require two or more baths, and, consequently, as many cop-dyeing machines, thus considerably reducing the output of ready dyed cops per machine. Unfortunately, the fastness of the substantive dyes against washing and milling is almost without exception so unsatisfactory that their application on cops is comparatively very limited.

The chemical reasons, if there are any at all, for the affinity of these dyes to the cotton fibre are unknown at present. It is well known that the cotton takes up these dyes from the dye-bath at or near boiling temperature, but this absorption arrives at a standstill long before the dye-bath is exhausted. It may even be found with certain dyes that prolonged boiling causes the cotton to again lose part of the dye which it previously absorbed. For the production of a certain shade with these dyes a knowledge of the percentage of colouring matter is utterly insufficient, the final result depending quite as much upon the concentration of the dye-bath, its temperature, and the time allowed for dyeing. We find, therefore, that a bath made up from 3 lb. of dye and 50 gallons of water produces a much stronger shade than a bath made up from 3 lb. of dye and 100 gallons of water. This important fact is not of the same consequence in yarn and piece-dyeing, where it is comparatively easy to dye up to sample either by adding more of the dye to the baths, or interrupting the process as soon as the desired shade is obtained. In cop-dyeing this is not practicable, even in the machines of Graeniger and Mommer, which operate with comparatively large quantities of cops at a time. The reason of this is that during the dyeing operation the cops are practically beyond the control of the dyer, and, further, that dyeing is done in these machines in only a minute fraction of the time which it requires in the open bath, so that before any alteration of the bath could be made the cops are already finished. If, on the other hand, such weak

dye-baths were employed that the production of the attainable shade would require as much time as has to be allowed in the open beck, namely, from 20 to 60 minutes, the output of all cop-dyeing machines would be so small as to render the process commercially impossible. It is, therefore, necessary to employ dye-baths of such concentration and temperature that the desired shade is obtained in the minimum of time. The latter is, as I showed in the second part of this paper, determined by the construction of the machine, and is identical with the duration of each immersion, which is six minutes in Mommer's machine, two minutes in Graemiger's machine, and half a minute in Crippin and Young's machine. Owing to the extraordinary shortness of each immersion in the last-named machine, generally four immersions are given to complete the dyeing process, which therefore requires two minutes altogether. The fact that in Crippin and Young's machine dyeing is done, so to speak, in a number of very small instalments is of very great importance. The dyeing process can be interrupted, if required, in one-twelfth of the time from Mommer's, and one-fourth of the time from Graemiger's machine, thus depriving cop-dyeing almost entirely of its awkward mechanical rigidity, which in many cases places the dyer in a rather helpless position. It is further worth mentioning that the depth of shade obtained with the same bath in different machines varies not inconsiderably, and will be found lightest in Mommer's machine, darker in Graemiger's, and still fuller in Crippin and Young's machine. An advantage of one machine against the other cannot be inferred from this fact, as proportionally stronger dye-baths will remove any differences of this description, although I might perhaps mention that the cops, when they are removed from the machines after dyeing, contain about 70 per cent. of their dry weight of dye-liquor, and the proportion of free or uncombined dye contained in this liquor of course increases in proportion with the strength of the dye-bath, and, if not washed out, causes the yarns to bleed excessively; if washed out it represents a not inconsiderable loss of dyestuff. It is, therefore, desirable to dye each shade in as weak a dye-bath as possible, whereby also very much clearer and brighter shades are obtained.

In each operation we abstract from the bath a certain quantity of dye which has become fixed upon the cotton, and a further quantity of dye contained in the 70 per cent. of dye-bath which is mechanically retained by the cops. In other words, in the process of dyeing we reduce the concentration of the dye-bath as far as the percentage of dye it contains is concerned, and at the same time we reduce the volume of the dye-bath, containing all its constituents, in proportion to the quantity of it mechanically retained by the cops. A further alteration of the concentration of the dye-bath is caused either by evaporation or condensation of steam. The former is always the case in Graemiger's and Crippin's machines; the latter is a particularly disagreeable feature of Koblenzer's machine. It is evident that in order to obtain all the lots dyed in succession, of the same shade, we must always, before starting the treatment of a new lot, bring the dye-bath to its original volume and concentration. The restoration of the volume is very simple in all those machines in which the volume decreases during the dyeing operation. If however, as in Koblenzer's machine, the volume of the dye-bath is increased, we can only bring it to its old concentration by adding to it fresh quantities of the dye and other constituents. The quantities to be added are, however, very difficult to calculate, and, moreover, the dye-bath is constantly increasing in bulk. For this I consider dilution of the dye-bath in working one of the greatest drawbacks a cop-dyeing machine can possess, as it introduces in its working an element of great variability and difficulty.

For the restoration of the concentration and of the dye-bath the following data are employed:—

1. The strength of the shade dyed, or percentage of dyeing; this factor is best experimentally established for every shade.
2. The quantity of dye-bath mechanically retained by the cops.
3. The evaporation taking place at a fixed temperature in dyeing given weight of cops.

The use of these data is best shown by giving an example which might be directly applied to Graemiger's, Crippin and Young's or Mommer's machines:

Original dye-bath: 1 lb. Benzopurpurine.	
4 „ Soap.	
4 „ Soda crystals.	
100 gallons of water.	
Dyed: 100 lb. of cops, 2 p.d. shade.	
Loss of dye-bath 2 lb. Benzopurpurine.	
Dye-bath me- chanically re- tained by the cops	70 lb. Water.
	— „ 1.5 oz. Benzopurpurine
	— „ 1.5 oz. Soap.
	— „ 4.5 oz. Soda crystals.
Loss of water through evaporation: 330 lb. of water.	
Total loss per 100 lb. of cops: 400 lb. of water.	
2 „ 1.5 oz. Benzopurpurine,	
4.5 oz. Soap.	
4.5 oz. Soda crystals.	

From this it follows that for every pound of cops dyed per operation, we have to add to the dye-bath a mother-bath consisting of—

1 lb. of water.
0.045 oz. Benzopurpurine.
0.045 oz. Soap.
0.045 oz. Soda crystals.

There is a slight error in this calculation, owing to the neglect of the specific gravity of the dye-bath. This error is so small that it is not worth considering, although there is no difficulty in eliminating it.

This question of replenishing the baths becomes much more complicated if the dye bath contains more than one of the substantive dyes, because they are not taken up by the cotton in the same proportions in which they are present in the bath. At first sight this difficulty appears so great that the dyeing of mixed shades on cops has been pronounced altogether impossible. If not altogether impossible, it certainly will offer enormous difficulties in machines of the type of Mommer's, where large quantities of cops are treated simultaneously, and where the cops are not at any time at the same stage of impregnation. This difficulty does not exist in Graemiger's or Crippin and Young's machines. The best way to arrive at the respective proportions of the mixed dyes taken up by the cotton is to compare the baths before and after dyeing colorimetrically. The results of this test, together with the total percentage of dye put on the cotton, enable us to calculate the necessary composition of the replenishing or mother bath.

I have recommended above the use of the colorimeter for baths containing more than one colour, and I may say that such an instrument will often be found of great assistance in the cop-dye house. There is, however, also a direct dyeing test for estimating the various proportions in which several dyes participate in a compound shade. In carrying out this direct test standard solutions of the various colours are prepared, and very gradually added to a weighed hank of cotton, which is kept in a boiling 30 per cent. strong solution of common salt. By this means only traces of the dyes remain in the bath, and the quantities of the different dye solutions which have been used to produce a given shade at once supply us with the figures showing the total percentage of dyes taken up by the cotton, as well as the proportions in which the various dyes are present. The method requires some practice, but the results are very reliable. In many cases it may be desirable to ascertain the correct management of a dye or mordanting bath by a short test. For this purpose a simple hydrometer often answers very well. It will be hardly necessary for me to observe that for the testing of hot or boiling baths in this manner hydrometers registering below 1.000 sp. gr. must be used.

Altogether it may be said that the difficulties of dyeing cops with benzidine or diamine colours are very small indeed as long as only single dyes are employed, and as long as not exceptionally heavy shades have to be produced. The difficulties in the way of dyeing compound shades with these colours are also of such a nature as to be readily overcome

by careful and judicious manipulation. These direct dyes, moreover, all dyeing in one single bath, and thus requiring one machine only to carry out the dyeing process, it will be easily understood why the cop-dyers paid them such particular, almost exclusive, attention. On the other hand, however, it was found, that very heavy, brown, blue and black shades cannot satisfactorily be obtained with these dyes, so long as the circulation of the dye-bath through the cops takes place in one direction only. Under this condition many of the cops will be found to be very unevenly dyed. This can be remedied by constructing the machines in such a manner that the circulation can be reversed between alternate immersions. Mommer's machine is the first which provided for this emergency in a practicable manner, although I am afraid that the advantage to be gained by this mechanical arrangement cannot be realised in Mommer's machine owing to the inevitable bulging of the cops in his machine in the direction of the circulation. On reversing the circulation this bulging would of course be bound to be thrown on the other side of the cop, and if such a rough treatment of the cops does not destroy their build altogether, it will certainly cause an outrageous amount of waste in the loom. Also Graeniger speaks in his patents of the reversion of the circulation, but there is little doubt that it is quite impracticable in his machine, and if applied would prove utterly unmanageable in regular working. Crippin and Young also provided their machines with a reversing arrangement, and their machine is at present the only one which works equally well in either direction. In dyeing very heavy shades in this machine irregularities in the circulation, say, from the outside to the inside of the cops, and caused through irregularities in the build of the cops, are most efficiently compensated by a reversion of the circulation during each alternate immersion, and the heaviest shades dyed in this manner are obtained perfectly even throughout each cop. This is a very important point in favour of Crippin and Young's machine.

Unfortunately all the substantive colours known at present, with the only exception of the Oxypheanine of the Clayton Aniline Company, possess the great drawback of bleeding most excessively in washing and milling. This goes so far that cotton dyed with these colours cannot even be said to be fast against hot water. The reason of this is no doubt that there is no chemical bond or affinity between these colours and the cotton fibre, the nature of their union being what Knecht called "rigid solution." The bleeding of these dyes could be prevented by converting them upon the fibre into fast lakes; but the only lake forming group in these dyes being the sulpho group, which is not capable of forming lakes fast against alkalis, the solution of this problem offers considerable difficulties, although I have reason to believe that they can be conquered. The above seems not to be in accordance with the well-known fact that Bayer and Co., of Elberfeld, by treating certain of their colours after dyeing with the solutions of certain metallic salts, preferably copper salts, obtained dyeings the fastness of which to washing is very satisfactory. But I am not of opinion that this treatment results simply in the production of a copper lake with the dye fixed upon the cotton. The shade of the colour is so much altered in this treatment as to suggest a much more complicated reaction. This treatment has only proved successful with the benzo-azurines manufactured by that firm. The bright blue shade they produce on cotton is thereby altered to a dull indigo blue, which is quite fast to soap as far as bleeding is concerned, but the soaping, and in fact any other alkali changes this dull indigo shade into a still duller puce. This renders the process a rather questionable success. Of more importance is the fact that some of these dyes can be converted into other shades by diazotising them upon the fibre and combining them afterwards with various phenols, naphthols or amines. The shades produced in this manner are all fast to washing and milling, many of them also exceedingly fast to light. This process, also an invention of Bayer and Co., cannot be considered as a solution of the above mentioned problem, as it results in shades more or less different from the original ones, and is only available for browns, dull blues, greys, and blacks. By a similar process Green obtained on cotton, dyed with his primuline, shades ranging from yellow to scarlet, maroon,

and purple. These are also absolutely fast to washing and milling; unfortunately they are wretchedly fugitive. The only drawback of these developed colours in cop-dyeing is the circumstance that they require three machines, corresponding to the three different baths used; but, on the other hand, it must not be forgotten that if the cop-dyers have to fight shy of the fast colours on account of the greater number of machines required for their production this new branch of dyeing would certainly be very narrowly confined in its field of working. Happily this is not so. It is evident that the number of machines which a dyer can afford to employ for the production of a certain shade is eminently a question of capital, that is of the price of a machine. If the cheapest machine should turn out to be at the same time the most efficient, the dyer will not be obliged to restrict himself to the dyeing of one bath colours. Of those machines that are at all efficient and generally applicable, Crippin and Young's machine is by a long way the cheapest and I am satisfied that it is also the simplest and safest in working.

IV.—MORDANT DYEING (ADJECTIVE) COLOURS.

A.—*Acid Dyes.*

The mordant-dyeing acid colouring matters are far superior in fastness to the substantive dyes, but their application in cop-dyeing offers difficulties of the most intricate description. Everything of course depends in the dyeing of these colours upon the level fixing of the mordant upon the fibre. In the first instance, to accomplish this, it is absolutely indispensable that the mordanting baths must always remain perfectly clear. Any disassociation of the mordanting salts taking place either by working the bath at too high a temperature, or by working the baths too basic, causes a more or less thick film to be deposited on the outside of the cops, which renders them altogether impermeable, and under any circumstances leads to such unevenness in the subsequent dyeing process as to make the cops absolutely useless. Another very serious difficulty is the great insolubility of most of the alizarine and other mordant dyeing colours in water. It is true all these colours will dissolve in alkalis or certain alkaline salts, but it seems that the affinity of these dyes in such solutions to the mordant fixed upon the cotton is at best considerably weakened and often practically altogether destroyed. Further, if the mordant has not been perfectly fixed upon the fibre, numerous small particles of it are washed into the dye-bath, remaining suspended there in the form of a colour-lake which eventually again is deposited on the outside of the cops, thus greatly impeding the circulation of the dye-bath and producing, moreover, unevenness of the worst kind. Taking all these points into consideration, it is quite evident that the dyeing of alizarine colours on cops is a matter bristling with difficulties, the ordinary methods of dyeing these colours failing us altogether.

The mordants we have to deal with in working with these dyes are the oxides of alumina, chrome and iron, the alumina mordant being undoubtedly the most obstreperous of the three. If we treat cops in a cold bath of acetate of alumina of the usual strength (from 6° to 8° Tw.) no precipitation of alumina either in the cops or in the bath takes place; the cops simply absorb about 75 per cent. of their own weight of the bath. Working at higher temperatures is prohibited by the disassociation of the acetate in the bath. If those impregnated cops are now dried, disassociation of the acetate of alumina takes place, alumina being fixed upon the fibre; but at the same time, owing to the evaporation of the water from the surface only of the cop, an osmotic action takes place by which undecomposed acetate of alumina is slowly but constantly conveyed from the central to the peripheral parts of the cops. When perfectly dry the cops are found to be mordanted all through, but the mordant is very unevenly distributed, being much stronger on the outside, than in the inside. As regards evenness better results are obtained by passing the cops impregnated in the alumina bath without delay through a soda-bath, but the mordanting is very weak, as it will be easily understood, that on circulating a soda-

bath through the cops already filled with the alumina bath, the latter is simply pushed out of the cop in front of the soda-bath, without mixing with the latter within the cop. By treating, however, these weakly mordanted cops with a solution of aluminate of soda, the mordant becomes much heavier owing to the property of the aluminate of soda to disassociate into alumina hydrate and caustic soda in the presence of free alumina hydrate. The alumina mordant so obtained is very well fixed on the fibre and very even, and although rather tedious on account of the many operations required, this is the only method so far to produce a strong and even alumina mordant on cops.

The baths being all used cold and no combination of any of the chemicals with the cotton, as in the case of dyeing, taking place, the loss of the bath consists simply in the quantity of bath absorbed by the cops, and this loss is made up in adding to the working bath from time to time from a mother-bath of exactly the same composition as much as is required to maintain the former at its original level.

The application of chromic mordants to cops is much simpler on account of the very decided affinity of chromium oxide to cotton, and especially the solutions of chromium hydroxide in caustic alkalis, known as chromites, readily give up their chromium hydroxide to the cotton fibre. It is sufficient to treat cops in an alkaline solution of chromium hydroxide at a temperature not exceeding 50° C. in order to obtain the cops very satisfactorily mordanted. The mordanting takes place much quicker at higher temperatures than with cold baths, and the strength of the mordanting is directly proportional to the concentration of the baths and about inversely proportional to the excess of caustic alkali employed for dissolving the chromic hydrate. These chrome baths have a very great tendency to spontaneous decomposition, this tendency increasing with the concentration of the bath and with the decrease of free alkali. It is also possible, however, to produce chrome mordants on cotton by means of neutral and basic chromic salts, the behaviour of which against the cotton fibre has been thoroughly investigated by Liechti and Snida, and was found to be greatly different from that of the similarly constituted alumina salts. Least suitable for the purpose are the neutral (violet)* chromic salts. By treating cops with the solutions of such salts, followed by a passage through some alkali or alkaline salts, chromic hydrate is precipitated upon the fibre, but it is only very imperfectly fixed. Better results are obtained by drying the cops after the impregnation with chromic sulphate, when 12.8 per cent. of the quantity of this salt absorbed by the cops firmly combine with the cotton fibre in the form of chromic hydrate. Owing, however, to the necessity of drying the impregnated cops, the mordanting has a tendency to become uneven, for reasons mentioned above. Basic chromic sulphates are much more satisfactory and, differing from solutions of basic sulphate of alumina, they can be heated without disassociation taking place. Treating the cops with solutions of such salts at a temperature of about 70° C., the cotton is very evenly mordanted and chrome mordants of about medium strength can easily be obtained in this manner. But it ought not to be forgotten that the dissociation of basic chromic sulphates is very considerably retarded, or even entirely prevented by the presence of sulphate of soda or potash. This makes it advisable to prepare such mordanting baths, not by partial alkaline decomposition of solutions of chromic sulphate or chrome alum, but by dissolving freshly precipitated chromic hydroxide in solutions of chromic sulphate. The strength of the mordant obtained with such baths depends upon the concentration of the bath, its basicity and temperature. The latter of course can easily be kept constant, but the maintenance of the basicity is a matter of considerable difficulty and requires one to start with a knowledge of the quantity of chromic hydrate fixed upon a definite weight of cotton, in using a bath of known concentration and basicity.

In the same manner as the chromic sulphate, the chromic acetates and chlorides may be employed. The latter give excellent results, especially if the commercial "Chlorchrome" of the formula $(Cr_2Cl_2(OH)_4)$ is used. Of course there also exists the difficulty with regard to the management of the baths, and although this difficulty is by no means insurmountable it is a matter requiring great care and foresight.

The iron mordants are in their chemical behaviour closer related to the alumina mordants than to the chrome mordants and accordingly disassociate more easily than the latter. For mordanting cotton the so-called nitrate of iron, *i.e.*, ferric sulphate, is almost exclusively employed. The neutral salt produces only very weak mordants, but by adding to it acetate of soda or carbonate of soda basic salts are obtained producing, according to their concentration and basicity, very strong mordants. The cops are treated in the cold baths, then left to lie for from 6 to 12 hours, when they are thoroughly washed. The mordants so obtained are perfectly even. Very frequently the iron mordant is used in the production of a "black bottom," by treating cops after first mordanting them with tannic acid or somac in the above mentioned ferric baths. This important mordant is very easily applied and it is only necessary to prevent the iron bath from acquiring a neutral or acid reaction. It is best kept alkaline by adding to it from time to time small quantities of acetate of soda.

Other metallic mordants are very seldom applied to cotton and are of no interest in cop-dyeing. But there remains a point of very great importance in connection with the mordanting of cops, namely, the washing of the cops after the operation of mordanting. I have repeatedly pointed out above that in cop-dyeing, in order to maintain the standard of shade through any number of consecutive operations, it is absolutely necessary to maintain the initial concentration of the working bath by means of a suitably composed mother-bath. Accordingly, under whatever conditions we dye or mordant, after withdrawing the cops from the machines they retain, as I have shown, a quantity of bath equal to about 70 per cent. of the dry weight of the cops. This quantity of bath, containing of course all the components of the working bath, must be washed out of the cops. This is important enough in withdrawing the cops from a dye-bath, as the mechanically-absorbed dye-bath, if dried in the cops would cause them to bleed and rub very badly. But still more important a matter is the removal of these mechanically-absorbed liquors after mordanting operations. If not removed, larger quantities of the mordanting bath will get into the following dye-bath, thus almost at once rendering it unfit for further use. The cop-dyeing machines are as a rule not very well adapted for the purpose of washing the cops, as they are mostly so constructed as to return the water circulated through the cops in the bath, which thus very soon becomes inefficient for further washing operations. There is, however, no difficulty to so construct the washing machines that the water after circulation through the cops is discharged from the machines.

Many of the mordant-dyeing colours are either totally insoluble or only imperfectly soluble in water. In order to employ them for cop-dyeing where always absolutely clear dye-baths are required, these dyes must be brought in solution by means of caustic alkalis, alkaline carbonates, soaps or salts possessing an alkaline reaction, such as acetate, phosphate or borate of soda. Soaps and neutral Turkey-red oil give very good results in many cases. The caustic alkalis certainly give the clearest solutions, but deprive the colours of almost all their affinity to the mordants, and the alkaline carbonates are scarcely any better. Ammonia can be used in a few exceptional cases only, as the primary lakes of many of the mordant-dyeing acid colours are soluble in it, so that by using ammoniacal solutions of such dyes not only no dyeing takes place, but very frequently the cops are altogether stripped of their mordants. This can be prevented by changing the primary mordant, previous to dyeing, into a compound mordant by means of acetate of lime or zincate of soda, compound lakes being insoluble in ammonia.

* The so-called "green modification" of chromic sulphates need not be considered here, as, according to recent investigations these compounds possess a constitution entirely different from that attributed to chromic salts.

For the dyeing of the mordant-dyeing acid colours on cops Erban and Specht's process (Ger. Pat. 5,057, 1890), might appear to be particularly well adapted. In this process the cotton is first treated with an ammoniacal solution of alizarine and then dried. This drying, which is absolutely necessary in order to fix the alizarine insoluble upon the fibre, makes the process unavailable for cop-dyeing, as on drying the greater part of the dissolved alizarine is deposited on the outside of the cops. The cause of this phenomenon has already been mentioned. If on the other hand the cops without drying are treated with alumina salts all the alizarine is washed out of the cop, owing to the great solubility of alizarate of alumina $Al_2O_3(C_{14}H_6O_3)_3$ in diluted ammonia.

B.—Basic Dyes.

Some of the basic dyes, such as Bismarck brown and chrysoidine, dye the cotton fibre without any mordant and can be used on cops in this manner for the dyeing of light brown and orange shades. Such dyes, however, possess very little fastness, the basic dyes only dyeing fast shades upon the tannin-antimony or tannin-iron compound mordants. For the production particularly of brilliant light shades alumina or tin mordants fixed with soap or Turkey-red oil are frequently used, but, as regards fastness to light and washing, colours dyed upon these mordants are very much inferior to the same shades on tannin mordants.

The mordanting of cops with tannic acid is carried out under the same conditions under which this operation is performed upon yarns, *i.e.*, at a temperature of from 80° to 90° C. As is well known the yarns remain in this bath for from 6 to 12 hours, or until it has become cold. In this manner the process is of course impracticable in cop-dyeing machines, but neither is there any necessity for it, as in all cop-dyeing machines working with a vacuum, the tannin is taken up by the fibre with astonishing rapidity, only equalled by the rapidity with which dyeing with the substantive dyes proceeds *in vacuo*. An immersion of one minute in *vacuo* in a five per cent. strong tannin solution at 90° C. produces the same effect as an immersion of four hours' duration with hanks in an open bath. The strength of the mordant entirely depends upon the concentration of the tannin baths, to which it is directly proportional. After the impregnation of the cops, air is drawn through them, as is usual after each bath employed for cop-dyeing, in order to remove as far as possible the excess of bath absorbed by the cops. These contain, then, first the quantity of tannic acid directly fixed by the cotton, and, further, the quantity of tannin contained in that portion of the bath which could not be removed from the cops by drawing air through them after the immersion. I have mentioned several times already that after impregnation in the cop-dyeing machine, hot or cold, the cops retain 70 per cent. of their dry weight of the bath, and this quantity cannot be removed by drawing air through them. According to this, 100 lb. of cops treated with a 5 per cent. strong tannin bath will retain 70 lb. of this bath, equal to about 3.5 per cent. of tannin. On extracting the tannin from such cops, 3.898 per cent. were recovered, so that about 0.5 per cent. of tannin were fixed direct by the cops. But there is no doubt that the whole of the tannic acid originally contained in the cops, in the form of mechanically-absorbed bath, is eventually assimilated by the cotton as the cops become cold. This assumption is supported by the fact that of the 4 per cent. of tannin contained in those cops only about 0.3 per cent. can be readily extracted, while for the complete extraction of the remaining 3.7 per cent. 21 hours are required. In precisely the same manner as tannic acid, all the other tannins used in dyeing may be applied. An important feature in the mordanting of cops with tannic acid is the extreme economy of the process as compared with the same operation on yarns. To produce a 1.5 per cent. strong tannin mordant on cops 1.5 per cent. of tannic acid is required, but to produce the same mordant on hanks 10 per cent. of tannic acid is used, or rather wasted.

The cops impregnated in a tannin bath ought to lie and cool for from five to 10 hours, but they must not be dried.

After lying for some time they are passed through a bath of tartar emetic and subsequently well washed. The various antimony fluorides and their double salts cannot be used in place of the tartar emetic owing to the enormous corrosion they cause if in contact with metals. If the cops have not been standing long enough before being treated with the tartar emetic, larger quantities of tannate of antimony are washed into the baths, rendering them unfit for further use or necessitating their filtration. It is, however, impossible to keep the tartar emetic baths absolutely clear, and it is therefore inevitable to prevent some of this free tannate of antimony from being filtered by the circulation of the bath upon the outside of the cops, which then in the subsequent dyeing results proportionately darker than the inside of the cops. This defect will not occur in Koblenzer's machine, on account of the filter-plates separating each layer of cops, while in Mommer's machine it will render the application of the basic colours an exceedingly awkward operation if not prohibit it altogether. In Crippin and Young's machine, this difficulty has been met with in a very simple and efficient manner by placing over each plate of cops in the machine a hood made from perforated metal and covered with some filter cloth, through which the tartar emetic bath has to pass before reaching the cops. If for the fixing of the tannin in the fibre a bath of ferrie sulphate is employed instead of a tartar emetic bath, the most important point is to prevent it from ever acquiring an acid reaction, by adding to it from time to time some acetate or carbonate of soda. After the fixing of the tannin, the cops are thoroughly washed and are then ready for the dyeing.

The dyeing of the basic colours on cops mordanted with tannin is exceedingly simple, especially if the dyes used do not possess any affinity for the unmordanted fibre. The concentration of the dye-baths requires almost no control, as the quantity of dye which can be fixed by the cops is unalterably determined by the percentage of tannin mordant which they contain. In the interest of greater purity of shade it is advisable to work with rather weak baths at a temperature of from 50° to 60° C. Rather more care is required if such colours like Bismarck brown, chrysoidine, rhodamine or indulin blue are used which possess a distinct affinity to the unmordanted fibre. It is necessary in this case to maintain the original concentration of the dye-baths in the manner already described. I have shown above that the exact quantity of tannin present in mordanted cops is always known and the equivalent quantity of any basic dye can be estimated with mathematical accuracy according to a method previously (this Journal, 1891, 794) described by me. From the data so obtained it is then very easy to calculate the composition of a suitable mother-bath. We will suppose the cops to contain 1.25 per cent. of tannic acid, and to be dyed with rhodamine B for which (*loc. cit.*) a tannin equivalent of 41 per cent. was found. If then we dye in a bath containing 5g of rhodamine per litre of water, the quantity of dye used for each kilogramme of cops is found as follows:—

1 kilo. of cops containing 12.5g of tannin	
	combine with : 29g rhodamine B.
1 kilo. of cops retain 0.7 litre of dye-bath	
	containing : 3.5g „

Dye used for 1 kilo. of cops : 32.5g „ B.

From this we find that after each operation, and for each kilogramme of cops dyed we have to add to the dye-bath 32.5g of rhodamine dissolved in the quantity of water lost in each operation through evaporation and absorption by the cops, the latter item amounting to 0.7 litre of water for each kilogramme of cops. The loss through evaporation shows its amount in the falling level of the dye-bath, and is very considerable in all those machines working under reduced pressure. In Crippin and Young's machine, for instance, the loss through evaporation amounts in boiling dye-baths to 3 litres of water for each kilogramme of cops. This loss of course decreases with the temperature of the baths, and in cold baths it is practically nil.

Such careful management of the dye-baths, as I have said before, is only required in the dyeing of the few basic colours which are capable of dyeing unmordanted cotton. Loss of colour from that source appears not to have been

accounted for in the above calculation, but it is represented by part of the colour retained by the cops in the form of mechanically retained dye-bath. The fact is that no dye is directly assimilated by the cops as long as there is any uncombined mordant, so that the direct dyeing capability of these dyes can only be exercised by that quantity of dye-bath remaining in the cops after each operation, which has been admitted already in the above calculation. As the effect of this direct dyeing action is proportionate to the concentration of the dye-bath, it is necessary to keep the concentration of the latter constant.

After dyeing it is absolutely necessary to wash all uncombined dye out of the cops, and in many cases it will be advisable to follow this washing by a second washing in a warm soap bath. Also a neutral solution of Turkey red oil may be used for this purpose.

C.—PIGMENT COLOURS.

By the term of pigment colours I understand all those dyes, which can be fixed on the fibre neither direct, nor by means of mordants, but only *in statu nascendi*. Dyes of this description are :—

- (a.) Developed colours ;
- (b.) Mineral pigments ;
- (c.) Vat dyes ;
- (d.) Aniline black.

Most of the dyes of these four classes are eminently important in the dyeing of cotton on account of their great fastness to light, washing, and milling.

a.—Developed Colours.

The term of developed colours is applied to azo colours produced upon the fibre from their components, but there is little doubt that also colours of other composition and the formation of which is based upon simple quantitatively proceeding reactions will be available before long. The formation of the azo colours depends upon the well-known reaction of some diazotised base with phenols, naphthols, amines, and their derivatives. In cotton-dyeing only such combinations command general interest which are absolutely insoluble in water, dilute alkalis, soap, and acids. The components used are either the so-called half-products of the coal-tar colour industry, or colouring matters themselves if they are either diazotisable or capable of combining with diazo compounds with formation of azo colours. We shall see later on that those especially of the substantive colours which can be diazotised are in their great importance in cotton dyeing only equalled by the alizarine dyes.

The formation of azo colours upon the fibre can be effected in two ways. We can first treat the cops with the solution of a diazo salt, and subsequently immerse them in the alkaline solution of some phenol or naphthol, or in the solution of some amine in hydrochloric, or preferably acetic acid, or we may first immerse the cops in the solution of the developer, and then treat them with the solution of the diazo salt. Both methods, particularly the last one, give very bad results upon cops ; in fact, they cannot at all be applied to them, although some Continental dyers employ them with very good results on piece-goods and yarns in the hank. The reason of the process giving bad results on cops lies in the fact that neither of the above-named compounds has any affinity to the cotton fibre, and are simply washed out of the cops in the process of developing the colour. To this must further be added, that solutions of diazo compounds are very unstable, and decompose so quickly as to make their use in cop-dyeing practically an impossibility. It is obvious that the process of forming azo colours upon the fibre can only be applied to cops if it should be possible to fix either the base to be diazotised or the developer upon the fibre after the manner of a mordant and fast against cold water. Developers of this kind are scarcely known,* nor could they be of much use in cop-dyeing, as the prospect of having to treat them in the baths of the exceedingly unstable diazo salts is not very

encouraging. Diazo compounds, which could be fixed upon the cotton fibre in the manner of a mordant, are, strictly speaking, not known, but there are some substantive dyes which can be dyed upon cotton in the well-known manners, and being amido-azo compounds of a certain order or constitution, they can be diazotised upon the fibre, forming diazo compounds insoluble in water, which by combination with amines, phenols or naphthols, form upon and in the fibre azo colours which are almost without exception fast to light, and all uncommonly fast to acids, alkalis, washing, and milling. Substantive dyes of this kind are primuline, diamine black B O, R O, and B H, diamine blue black E, diamine brown V and R, cotton brown A and N.

These dyes are dyed upon the cops in the manner before described, and the dyed cops are then well washed. This is of great importance, as otherwise the dyes finally obtained would rub off in an excessive degree. It is advisable to use warm water for washing if the cops have been dyed with colours difficultly soluble in water, such as diamine black R O for instance, otherwise cold water may be used. The perfectly cold cops are then treated in the diazotising bath, containing about 0.5 lb. of nitrite of soda and 0.9 lbs. of hydrochloric acid (1.50 sp. gr.) in every 10 gallons of water. It is desirable that these baths should always contain about the same quantity of free nitrous acid. The quantities of nitrite and hydrochloric acid to be added to the bath after each operation are calculated in the identical manner as the mother-baths used in dyeing. The diazotised cops are carefully washed, and treated in the developing baths without delay. The latter may with advantage be kept more concentrated than is usual in hank- or piece-dyeing; solutions containing from 3 to 5 per cent. of the developers answer very well. Of course after developing the cops are washed again.

Yarns dyed with primuline produce in this treatment, with various developers, fine shades of yellow, orange, scarlet, maroon, brown, and purple, which are all exceedingly fast to washing. Unfortunately their fastness to light is worse than bad, and I have no doubt that the discovery of a substitute for primuline would amply repay anyone for the trouble of searching for it. The developed colours obtained with the above-named or Cassella's diamine colours are also absolutely fast to washing and milling, and at the same time they rank, almost without exception, amongst the colours which are fastest to light.

(b.)—Mineral Pigments.

Before the introduction of the substantive dyes and of the coal-tar colours generally, the colours of this group were of very considerable importance in cotton dyeing. At present they have only their cheapness and, in some cases, their great fastness to light to recommend them. It is very doubtful, however, whether in cop-dyeing they will assume even the moderate importance which they still possess in hank dyeing.

Of all the mineral pigments used in cotton dyeing the "iron buff" is probably the most ancient. It is produced upon cops in the same manner and with the same materials as the iron mordants, namely, by treating the cops with cold solutions of basic ferric sulphate, and a subsequent passage through soda carbonate. In dyeing in this manner light "Naunking" shades, they become frequently uneven in the following soda bath. To avoid this the soda carbonate bath may be omitted altogether, instead of which a small quantity of gaseous ammonia is drawn through the cops. This operation offers no difficulty in most machines, and directly after the ammonia treatment the cops can be washed.

More important than the "iron buff" are the chrome yellows, which, even to this day, are largely used in hank dyeing, although there is no scarcity in yellow cotton dyeing colours. The chrome yellows are dyed by first handling the cotton in a solution of some lead salt, preferably sugar of lead, and subsequent treatment in a bath containing bichromate of soda or potash and sulphuric acid or some sulphate, either sulphate of soda or alumina. The dyeing of this yellow on cops is exceedingly difficult. Of course the impregnation of the cops with the solution of

* Chrysoidine could be used in this manner, as it is capable of combination with diazo compounds.

the lead salt is simple enough, but in the subsequent operation with the chrome bath large quantities of lead chromate are unavoidably washed out of the cops into the bath, rendering it at once unfit for further use. This difficulty might be avoided by fixing the lead salt upon the fibre in an insoluble form; for instance, by impregnating with the lead salt cops previously mordanted with tannic acid. But this would be found too expensive. Attempts to fix the lead salt by treating the impregnated cops with gaseous ammonia, or alkaline sulphates, or carbonates, gave very unsatisfactory results.

Prussian blue is easily obtained upon cops by treating cops mordanted with ferric sulphate, after washing them in an acidulated bath of ferrocyanide of potash. The blue shades so obtained, although very beautiful, are not very fast to light and still less fast to washing.

Cadmium yellow, arsenic orange, and antimony orange, which are fixed upon the fibre in the form of their sulphides, also the brown manganese pigments or bistres, are very little used at present, partly owing to the poisonous nature of some of them, and there is no prospect that these colours will ever become of any importance in cop-dyeing. Suggestions as to applying these colours to cops would therefore be useless.

From the above it will be seen that mineral pigments are of very little, if of any, importance for cop-dyeing. In most cases the baths are rendered useless after the first operation, owing to the great quantities of loose pigment forming in them.

(c).—*Vat Dyes.*

There exists a number of natural and artificial colouring matters which are capable of forming a "vat" suitable for the dyeing of cotton goods, but only the indigo vat and the indigo-indophenol vat are of such importance as to be worthy of consideration with regard to their application to cop dyeing. The dyeing of indigo on cops is, of course, in the first instance a question of the reducing agent to be employed, only perfectly clear and limpid vats being applicable at all. For this reason all those vats working with insoluble reducing agents, such as the ferrous hydroxide (ferrous sulphate) vat, the zinc-dust vat, or the fermented vats, cannot be used. Of course it would be possible to filter from the insoluble sediments in these vats the clear solutions of indigo white, but as these solutions would then no longer be in contact with reducing agents, oxidation of the indigo white would result in a considerable degree during the circulation of the vat in the machine and through the cops, which would be badly dyed, and contain a large amount of loose dye. To avoid this we shall have to use a vat which is working with a soluble reducing agent, and which accordingly accompanies the indigo white everywhere. This condition hydrosulphite of soda fulfils in the most excellent manner, and, indeed, all attempts that have been made up to now to dye indigo upon cops have been made with the hydrosulphite vat. The preparation of this vat is so well known that we need not concern ourselves with it, and, moreover, there are now concentrated solutions of hydrosulphite in the market which reduce the preparation of the vat itself to a very simple operation.

The dyeing of the cops by means of this vat is performed by drawing the absolutely clear vat one or more times through the cops, the cops between each immersion being submitted to oxidation by drawing air through them. The formation of some indigo blue outside the fibre is unavoidable in this process, nor can this indigo be prevented from getting subsequently into the baths. Most of it is there reduced again, but it is certainly advisable to provide some filtering arrangement, so as to prevent any of this suspended indigo blue from being deposited upon the outside of the cops. The oxidation of the indigo white fixed in the cops appears to offer no difficulties whatever, and from a purely chemical point of view this is indeed so, the mere drawing of air through the cops being quite sufficient to produce complete oxidation. It is somewhat surprising, however, that the blue obtained under these conditions is greatly lacking in beauty and "bloom."

Another process of performing the oxidation in indigo dyeing has lately been recommended by Flick and

Michaelis, who propose to immerse the yarns in hot ammoniacal water. Also in this method absorbed atmospheric oxygen is the oxidiser. The process, which is said to give excellent results, can also be adapted for cops.

Somewhat remarkable is the great tendency of the indigo vat to dye the cops very unevenly, and also frequently numerous lighter or even white spots are noticeable. These latter invariably appear if the cops are dyed in the grey state. This, of course, is scarcely surprising and can be stopped at once by submitting the cops previous to dyeing to an efficient scouring in alkaline liquors. Much more difficult is it to secure evenness of dyeing, especially in the high-priced dark coppery shades, and I do not believe that the production of these shades can be carried out in a satisfactory manner on any one of those machines circulating the dye-liquor in one direction only through the cops. The unevenness disappears at once if we reverse the circulation alternatively, and the great ease with which this can be done in Crippin and Young's machine I consider one of its most noteworthy features.

For the dyeing of cheap indigo shades the yarns are given, before the vat treatment, a "bottom" of logwood or some suitable coal-tar colour. This principle, of course, is also applicable to cop-dyeing. But it must not be forgotten that it is almost impossible to wash cops as thoroughly as yarns or piece-goods. For this reason only such dyes ought to be employed for these bottoms which are absolutely fast to washing and do not bleed in contact with alkaline liquors, otherwise the vats soon get badly contaminated by dye bleeding off the cops, and I need hardly remark that indigo shades dyed in vats contaminated in this manner lack more or less in brightness. But, altogether, I believe that in the majority of cases it is very much to be preferred in cop-dyeing to produce the cheap shades by topping light indigo shades, instead of dyeing them on a bottom. Better results are obtained in this manner and any possible contamination of the vat is avoided, which is a matter of no small concern.

The indophenol vat if used by itself is scarcely capable of dyeing cotton in a satisfactory manner, the shades being altogether wanting in body and brightness. If, however, a vat be employed containing indigo and indophenol in certain proportions excellent results are obtained, the shades dyed being brighter than with indigo alone and much faster to rubbing and soaping. At the same time the fastness to light is quite as great as that of pure indigo. The management of this vat, as well as its preparation, is identical with that of the indigo vat, but there is, of course, a very substantial economical advantage in the use of the mixed vat, indophenol being so much cheaper than indigo; and as, on the other hand, these mixed shades are in every respect at least equal in fastness to the pure indigo shades, this indigo-indophenol vat deserves much more attention than it has hitherto obtained.

(d).—*Aniline Black.*

The production of aniline black on cops has not passed yet beyond the experimental stage, but we shall not have to wait long for the solution of this important task.

The method of aniline-black dyeing, known as the one-bath process, which is so extensively used in yarn and piece-dyeing, cannot be applied to cop dyeing owing to the unavoidable formation of free aniline black in these baths. Considering the small quantity of cops dyed in one operation in a comparatively very great volume of dye-bath, which applies to all cop-dyeing machines, the one-bath process, through the spontaneous decomposition of the baths, would be exceedingly expensive, and complicated filtering arrangements would be required in order to prevent large quantities of loose aniline black from being deposited on the outside of the cops.

Oxidation aniline black offers no difficulties of the above-mentioned description, but it has not been produced yet on cops in a satisfactory manner. The impregnation of the cops with the bath is, of course, an easy matter, but the difficulties begin with the drying and ageing of the cops, which in the manner previously referred to, causes the constituents of the bath to migrate from the inner to the outer

parts of the cops. If then, subsequently, the aged cops are oxidised in the bichromate bath, a very uneven black is obtained. Apart from this difficulty, the ageing of the impregnated cops proceeds very satisfactorily provided the temperature and moisture of the air be judiciously regulated. Too high a temperature or too low a moisture of the air in the ageing chamber will tender the fibre more or less; and I may say that cops want in this respect more care and precaution than hanks or piece-goods, owing no doubt to the heat accumulating through the oxidation in so non-conducting a material as cotton cops. A temperature of 15 C. on the dry and from 38 to 10 C. on the wet bulb ought never to be exceeded. An excellent black is obtained by the use of aniline fluoride, but the starch which is contained in the aniline-black bath as recommended by Messrs Bayer & Co. must be omitted, it being impossible to force such a bath through the cops. Of the beneficial action of the starch there is, however, no doubt, and I recommend therefore to use in its place for cops dextrine, glucose or glycerin. Unfortunately aniline fluoride possesses properties which render its application in the present cop-dyeing machines absolutely impossible. Wherever this salt comes in contact with iron, copper, brass, phosphorbronze, lead, silicates, (glass, enamels, earthenware) it exerts a most vehement corrosive action.

Steam aniline black applied to cops shows the same difficulties as oxidation black. Also the steaming of the dried cops is much more difficult as might be expected. Considering however, that this black is by far less injurious to the cotton fibre than the oxidation black, I have no doubt that the difficulties preventing its application to cops will be conquered before long.

Some recent aniline black patents of Jagenburg (Fr. Pat. 220,031, 1892), and Mommer are not likely to become of importance in cop-dyeing owing to the unavoidable turbidity of the baths used in these processes, while the casein used in Mommer's process will produce such viscous baths, that it will be almost impossible to force them through the cops.

DISCUSSION.

The CHAIRMAN said Dr. Weber had explained the subject of his paper in such a clear manner that it could not fail to be intelligible to everyone. Still it was a subject so entirely out of the range of ordinary experience that they could hardly expect him (the Chairman) to make any remarks upon it. Looking at the subject from a general point of view it seemed to him that the process depended much more upon mechanical than upon chemical principles. The great difficulty seemed to be to get uniform shades of colour through the dense masses of raw material, and he presumed this was the great difficulty which presented itself to those gentlemen who had occupied themselves in the construction of these machines. He was very much interested in Dr. Weber's remarks about substantive colours as applied to cotton. He had always been of opinion that cotton had no chemical affinity whatever to any dye, and he was very much interested with the cursory remarks with regard to substantive dyes, in the course of which the author stated that the dye was contained in the cell which exists in the centre of the cotton fibre. He would like Dr. Weber to explain how any colouring matters could enter the cotton fibre without affecting the surrounding substance.

Dr. WEBER, in reply to the Chairman's question with regard to the penetration of the dye into the cavities of the cotton, said he had absolute proof of this in some microscopical slides he had prepared showing a section of the thread with the interior entirely filled with dye, but how the dye got into the cell he could not say. It might be that the penetration was due to an osmotic process, but this might hardly be considered a satisfactory explanation. In order to dye cotton perfectly with the substantive dyes, they had to get the dyes into the cavities of the cotton, but before this could be done the air or water in the cavities of the cells must be removed either by producing a vacuum or expelling the air or water by pressure.

In reply to Mr. Thomson, he could only say that dyeing cotton in the grey was certainly more difficult than

dyeing bleached cotton, for reasons he could not fully explain. With regard to Mr. Thomson's further remarks as to the boiling off of the substantive dyes, he could give as an absolute fact within his experience that in a case where the ordinary wood dyes were used they were given up in favour of the substantive dyes. In dyeing drab shades in this manner, dyeing was started at a very low temperature in order to prevent unevenness of the dye. The black fell on splendidly, but when they proceeded to fix it by raising the temperature all the colour came out again. His explanation of this was that dyeing with substantive dyes was not dyeing at all—it was simply staining. They got the colour inside the cotton fibre and there it stuck, but as soon as they treated the hank with water some of the dye came out. They were never able to abstract the whole of the colour. There always seemed to be two antagonistic attractions with regard to these dyes, preventing the complete exhaustion of the dye-baths; and he believed Witt's well-known theory of dyeing was based upon observations made in the dyeing of substantive colours. They could always prove a substantive dye to be present in the cotton in an absolutely free state. If they treated benzidine colours with acid they would change colour. For instance, Congo red turned blue; because while the free acid of Congo red was blue, other benzidine colours had colour acids of the same colour as the dye itself; and that was the reason why some of them are said to be fast to acids, which they are not in a strictly chemical sense. With regard to Mr. Thomson's remark as to dyeing the cotton before it goes on the cops, this was rather a large demand. He would remind Mr. Thomson of the tremendous speed at which the thread travelled in the mule, and which would give no reasonable time for the dyeing. In winding the cops into hanks waste was incurred by breakages and otherwise, and in winding the hanks back into pirns there also was loss. If they dyed in the cop there was no shrinkage possible, and, further, there was no appreciable risk of breakage. In reply to Mr. Hurst he believed he had noticed the effects of some peculiar substances in cotton (the nature of which he did not know) which prevented the dye from entering the fibre.

SESSION 1892-93.

Notices of Papers and Communications for the Meetings to be sent to the Local Secretary.

Meeting held Thursday, December 8th, 1892.

PROFESSOR P. P. BEDSON IN THE CHAIR.

THE VALUATION OF SULPHURIC ACID, CHIEFLY FROM A COMMERCIAL ASPECT.

BY JOHN MORRISON.

THOUGH the production of pyrites vitriol is a process not less than fourscore years old, I question whether there is a manufacturer to-day who can prove that he knows, by any positive method of estimation, and within, say, 10 per cent. of its present commercial value, what his acid costs him per ton; and it is something to be regretted that in detailing Leblanc process results, the only recognised practical course is to ignore the vitriol chambers altogether, and to tabulate merely the quantity of salt-cake or alkali which a given amount of sulphur consumed will produce. This—even if in other respects unobjectionable—is somewhat unfair, inasmuch as it debits to sulphuric acid instead of to sulphate of soda—or in other words to *vitriol made* instead of to *vitriol consumed*—the acid volatilised in the salt-cake process.

There are of course considerable difficulties in the way of estimating large process bulks, and chamber areas of liquid of such variable density and temperature; for even supposing—which is very far from the case—that the acid in a single chamber is of uniform specific gravity, a “dipping” error of a single tenth of an inch may involve a discrepancy of 10 or 15 cwt. of “O.V.”

Yet bearing in mind, that in many processes cheap vitriol is the real hinge upon which financial success turns; that, as regards the chemical manure trade, the sale of superphosphates is little more than a dry way of selling sulphuric acid; and that the vitriol traffic in this country is of considerable importance; it must surely be regretted that some standard and universally acceptable method has not ere this been devised for estimating, otherwise than negatively, and within reasonable limits of accuracy, the cost of a ton of vitriol in terms of itself. For until the manufacturing cost of vitriol becomes correctly determinable, the sale price can never be perfectly equitable.

One of the first difficulties perhaps, is an agreement as to the calculative *standard of strength*. If absolute H_2SO_4 be fixed on, then there is the objection that it is practically non-existent, and that its specific gravity is uncertain; and in fact any strength over $150^\circ Tw.$ has the disadvantage of

representing what I might term a *rectified* rather than a *chamber* or a *Glover tower* standard. This objection possibly is not serious, yet it would certainly have some weight where the manufacture and sale of both these acids was simultaneously carried on. But whatever universal standard be selected, it should at all events not only meet both buyers' and sellers' views, but be one to which all acid process results could be systematically reduced. I question, therefore, whether any other than an “O.V.” or absolute H_2SO_4 standard is ever likely to be generally enforced.

Then there is the *hydrometer* difficulty. The hydrometer in common use is, I am afraid, distinguishable rather by its cheapness than by its reliability; for when compared with standard instruments, errors of 2° or 3° are by no means uncommon. And besides this, its paper scale—as is well known—occasionally glides from its allotted position, and under the most favourable circumstances its register is, I am afraid, decidedly against the vitriol consumer.

Next come the *calculating table* difficulties, and it is something of a disgrace that no standard tables are in universal adoption. Probably the best published tables are those of Lunge and Isler, given in the Journal of May 1890. These have been, I believe, introduced into some of the U. A. Co.'s works, but the tables in more general use are for the most part extremely antiquated. Indeed all the tables with which I am familiar yield excessive results for commercial acid, because of their ostensible reference to chemically pure vitriol only. If there were but one existing table, the position would not be so bad, but there are to the front not only the tables of various original investigators, but sundry illegitimate offspring of which the parentage is exceedingly difficult to trace. And surely the time has arrived for the elaboration or selection of a set of tables fairly applicable to the denitrated Spanish pyrites of commerce, the purity of which at ordinary merchantable strengths cannot be very variable.

The tables in use are not only discordant, but exhibit also unequal ratios of variation between successive specific gravities. That any substantial irregularities really exist, seems hardly likely, and if they do not, surely their elimination from accepted tables is highly desirable.

As illustrating these discrepancies, I may take five of these tables: A = one used in a Tyneside works; B = Kolb's table as given by Lunge; C = Otto's table in Bayley's Chemist's Pocket Book; D = an unidentified table from the Chemical Trade Journal of September 24, 1892; and E = the Lunge and Isler table already mentioned. From these several tables, therefore, we obtain the following particulars:—

° Tw.	Specific Gravity.	Lb. of H_2SO_4 in One Cubic Foot.					° Tw.	Increase in Lb. H_2SO_4 per cubic Foot.				
		A.	B.	C.	D.	E.		A.	B.	C.	D.	E.

Tables B, C, and E deal with a temperature standard of $15^\circ C.$ (= $59^\circ Fahr.$), but the standards for A and D are not stated. Also tables A, C, and D assume a cubic foot of water to weigh 62.36 lb. or thereabouts, while tables B and E put it at $62\frac{1}{2}$ lb.*

For commercial purposes the *temperature standard* of this country is $60^\circ Fahr.$ And this will be perfectly convenient so long as the Fahrenheit scale remains in favour.

The *water standard* also for that temperature is $62\frac{1}{2}$ lb. per cubic foot, which is equally convenient, if only it be reasonably accurate. That it is so I am unable to say. But inasmuch as the steam entering the sulphuric acid chambers, either direct or from the Glover towers, cannot vary very much in purity, I think the water standard might with advantage be reinvestigated and verified, as it is in all probability somewhat high.

The handling and transit of sulphuric acid are now accomplished by far different methods from those prevalent 25 to 30 years ago. At that time delivery in fragile earby tubs, weighing nearly half as much as the liquid they

* Some manufacturers I may remark, use as a sort of calculative starting point 1 cub. ft. $120^\circ Tw.$ acid = 100 lb., and contains 70 lb. “O. V.”

contained, was customary. But now carboys have to a large extent given place to wrought-iron tanks lined with lead, or, more recently, to unlined tanks of steel, from which the acid can quickly and tidily be discharged by gravity or compressed air.

This change has necessitated the estimation of weight by gauging and calculation, and it is here that a correct water standard, as well as an accurate hydrometer observation, is of importance.

Having first carefully taken the strength of the acid, and ascertained the quantity in cubic feet discharged into the tank, it is only necessary to multiply the latter by the lb. of water in 1 cubic foot at 60° F., and the result by the specific gravity calculated from the hydrometer strength. This gives the dead weight in lb., so that the only question left is the determination of the selling strength. Here a temperature correction is usually needful, because the acid is presumably sold on the definite temperature basis of the water, in relation to which the acid weight has been computed. If this were not so, it would be to the seller's interest to refrigerate the acid, and to the buyer's to have it delivered hot. Hence commercially the acid is assumed to rise 1° Tw. in strength per 10° F. fall (or vice versa) in temperature. And in accordance with this, all necessary strength adjustments must be made. But of course the corrections must be made *after* the ascertainment of the weight, because the weight of acid obtained (as just mentioned) from the specific gravity *at the actual temperature at the time of observation*, gives the weight as compared with the 60° F. water standard adopted, and variations in the acid temperature being inversely proportionate to variations in the specific gravity, the two neutralise each other, and so have no ultimate effect upon the acid weight.

So far, therefore, the vitriol selling business is pretty fair sailing. But the chief difficulties are yet to be described.

If sulphuric acid be sold (as it almost invariably is) at so much per Twaddell-degree-ton, I think it may fairly be assumed that Chamber and Glover tower acids possess commercially a purely H_2SO_4 strength pro rata value, and that the loss of nitrogen to the manufacturer selling chamber acid (from at all events the strong chamber)

something like counterbalances the extra expenses involved by the sale of denitrated vitriol.

I am of course aware that this does not fully represent matters in the case of a salt-eake and bleaching powder maker disposing only of his surplus vitriol, inasmuch as for decomposing purposes the stronger acid of the Glover tower is naturally the acid he prefers retaining for his own use. But with this trifling exception, which is technical rather than commercial, I think the assumption may pass. In fact, that acid from say 120° to 150° Tw. possesses commercially an even *pro rata* H_2SO_4 strength value, is proven to a pretty conclusive degree (though in a negative way) by the adoption of high standards in those selling centres where acid is cheapest. For vitriol has to my certain knowledge been sold this year in quantity at 2s. 6d. per ton less for 140° Tw. in one district, and only 3d. per ton more for 148° Tw. in another district, than the lowest price at which I believe it has been sold in a third district for 120° Tw.; all of these districts being of substantially equal importance, and the last-named—as regards the economy of production—being, I am satisfied, the most favoured of the three.

Sulphuric acid then is sold upon a Twaddell basis which varies in different localities. In some, 120° Tw. prevails, and in others, strengths varying from 140° to 150° Tw. are customary.

Occasionally inequalities in delivered strengths are reduced to the fixed basis before invoicing. But far more usually variations of strength are charged at the *pro rata* price per Twaddell degree (or unit) ton.

Thus, if the agreed price be, say, 22s. 6d. per ton of 120° acid (= 2½d. per unit), the cost of the acid = 24s. 4½d. on 130°; 26s. 3d. on 140°; 28s. 1½d. on 150° Tw.; and proportionally as regards the strengths between.

The reduction-to-a-fixed-standard method is, however, by far the best, as a variety of invoicing strengths greatly confuses and prejudices the manufacturing accounts of both buyer and seller.

But to show the effect of the already quoted tables upon the usual method of acid selling, I will give the figures from 100° to 150° Tw. at 10° intervals on the price basis just mentioned.

Tw.	Cubic Feet in one Ton of Acid.					Lb. of Absolute H_2SO_4 in one Ton Acid.

* Of course in the two *below basis* strengths given in the first section of this table, the variation is in the same direction (*i.e.*, against the seller) as that in the second section of the table.

These figures shew an average of $\text{£}1\ 6\ 7\frac{1}{2} = 1\text{s. } 6\frac{1}{2}\text{d.}$ per ton against the buyer, where the standard is 120°Tw. , and the delivered acid is 150°Tw. ; or $\text{£}1\ 0\ 8 = 1\text{s. } 11\text{d.}$ per ton against the seller where the standard is 150°Tw. , and the delivered acid is 120°Tw. And as will be also observed, the error is slightly erratic in one or two of the intervening strengths.

The discrepancy is of course due to the degrees Tw. varying one-third more rapidly than the percentage of O.V. in the successive specific gravities which they indicate. And the remedy appears to me to lie in the direction of the entire abolition of the Tw. degree pro-rata method of sale; the selling universally on H_2SO_4 ; and the correction of all acid deliveries before invoicing to their H_2SO_4 or "O.V." equivalent.

It may be said that the discrepancy is not serious, but it *will* be serious when the price of pyrites is advanced, and that of vitriol follows suit. Indeed it is already serious in the chemical manure trade at a time like the present, when every penny saved in the production of a ton of superphosphate is of importance. And in any case, the mere pecuniary assessment of the value of chemical discrepancies is too often a depraved and unjust judgment. Besides, it must be recollected that the maximum possible error is not the *difference*, but the *sum* of the several possible erroneous elements contributed by the use of inaccurate hydrometers, incorrect water-standards, and doubtful tables never intended for commercial oil of vitriol.

It may be also urged that the selling basis is usually fixed at somewhere near the average delivered strength of the particular contract or district. But vitriol is frequently sold on a simple minimum Twaddell guarantee, with no over-strength restrictions, so that the deliveries oscillate between the acids of the chambers or Glover Towers, just as suits the variable convenience of the manufacturer. To most large buyers, the higher sp. grs. are solely of consequence from the saving in transit which they secure. And what chiefly rules the minimum strength is the action of acid under 126° to 130°Tw. upon the steel tanks in which deliveries are made. Indeed to the manure maker, strengths approaching 140° to 150°Tw. are positively objectionable, inasmuch as strong acid is not quickly miscible with water, and so results in irregularities in the superphosphates for the production of which it is supplied.

There can then I think be no question that vitriol should universally be sold and invoiced at per ton of "O.V."; the margins of delivery strengths being arranged to suit both buyer and seller; and of course an extra charge being made for rectified and non-arsenical acids; and carriage being charged in all cases on dead weight. It may be pleaded that this would introduce extra calculations, but they would be avoidable with suitably prepared reduction tables. And even for some slight additional tax on clerical forbearance, there would be the abundant reward of greater accuracy and consistency in the process and costs books of both makers and consumers.

But in the event of such a wholesome reform being agreed on, all the more need would arise for standard calculating tables, showing as far as may be evenly progressive variations of H_2SO_4 between the several Twaddell degrees. And towards the furtherance of such a reform, I for one would like to see the appointment of a strong representative committee of acid manufacturers, sellers, and purchasers, to legislate not only upon the tables, but upon the hydrometers, and the temperature and water standards of the future.

MR. JAS. SHARP IN THE CHAIR.

PRIMITIVE MODES OF DYEING.

BY PROFESSOR J. J. HUMMEL.

(Abstract.)

PROFESSOR HUMMEL gave a communication with regard to primitive modes of dyeing, which he illustrated by specimens. He first described the methods of dyeing practised by the Timanees and Mendis races of Africans living about 200 miles inland from Free Town on the Sierra Leone coast. For vat-blue on cotton yarn they employ the leaves of a large forest shrub, *Lonchocarpus cyaneus*, which are rubbed in the hand till they become blue, and then dried. In use, the dried leaves are mixed with water and the ashes of some plant which no doubt yields the necessary alkali, so that in principle the process is similar to that employed in Europe. Yellow and brown cotton are dyed by simply steeping in infusions of certain barks, the origin of which is unknown. The natives have no knowledge of the use of mordants, and do not apply camwood, which abounds in the district, although they have no red dye.

A brief description of the methods practised by the Maoris (this Journal, 1, 1882, 170) was next given, and samples of dyed mats, of the barks used, and of the black mud of certain swamps were shown. The barks yield small percentages of tannic acid, and the mud contains iron, partly in solution. The colours produced on the *Phormium tenax* fibre are various shades of grey and black, and the methods are interesting as showing in all probability the origin of the application of mordants, the principle involved being that still in use in Europe for the dyeing of tannin and iron blacks.

The "Batick" dyeing of the Javanese, and the "knot dyeing" of the Hindoos were also described and illustrated by specimens. In the first of these the dyeing of certain portions of the fabric is prevented by a wax resist painted on by hand; in the second by tying up with thread; and in both cases effects are produced which prove impossible to imitate satisfactorily by the processes in ordinary use in Europe.

DISCUSSION.

The CHAIRMAN commented upon the specimens of primitive dyeing exhibited, and made mention of methods adopted in England to achieve the same results. The method of "knot-dyeing" finds a limited application here, being used to mark the ends of the pieces with symbols indicating the quality of the material, or with the trade-mark of the manufacturing firm. The goods for the Java market are mostly in loose colours, "steam-work" being largely used.

Mr. RAWSON inquired how the fermentation of the dye-stuff was started on the West Coast of Africa.

Mr. SLATFER thought that the "alum-water" obtained by the West Africans from the ashes of the leaves of a certain tree could hardly contain alum, clubmoss being the only plant at present known to absorb aluminium.

Mr. F. W. RICHARDSON enquired if there were two separate fermentations in the process of indigo-dyeing employed by the natives of West Africa. Had the microbe of the indigo ferment been isolated?

A Member asked how the black in the Japanese specimens were obtained. It had rather the appearance of a brown possibly owing to fading of the colour.

Mr. PROCTER remarked that the tanekeha bark used for dyeing yellow in New Zealand was identical with the "golden-tan" bark used in this country for dyeing leather, especially kid.

Professor HUMMEL, in reply, stated that he had no information as to how the fermentation of the dye was induced on the West Coast of Africa. As to the "alum-water," mordants were unknown in this district, and it was probably the alkali in the ashes of the leaves that acted as a developer of the dye. In the indigo-dyeing there were two distinct fermentations: one when the leaves were rubbed in the hand and stored, the indican being broken up and indigo-blue formed; and a second when the leaves were steeped in water along with the fabric to be dyed: in this latter process the indigo-blue was reduced and rendered soluble. As to how the black in the Japanese specimens was obtained he could not say; Chinese black was not dyed, but painted on.

Mr. RAWSON then described a new form of dyeing-vat designed by Messrs. Smith and Whittaker (see Journal of the Society of Dyers and Colourists, January, 1893). At one end the dyewood is contained in a perforated box, and at the other steam is blown in, and the water is thus heated to boiling, and a current created which is directed so as to flow over and through the fabric to be dyed, and then through the dye-wood in the box and back again. If the water is already boiling when fresh wood is put in, 60-66 per cent. of the colouring matter is removed in four minutes.

Obituary.

WILLIAM NATHANIEL EVANS.

A MEMBER OF THE SOCIETY OF CHEMICAL INDUSTRY.

WILLIAM NATHANIEL EVANS, of Bristol, was born in 1826, at Ottery St. Mary, and came of an old Devonshire family. The greater part of his life was devoted to the manufacture of leather, but his strongly developed scientific tendencies led him early to study chemistry, and to apply it to the trade in which he was interested and in the technology of which he became a considerable authority. He started, and for some time edited the journal *Leather*, and was the writer of the article on "Leather" in Mackenzie's "Chemistry applied to the Arts and Manufactures," and also of a very useful text-book on "Burr Tanning" and made and published many analyses of new tanning products, and especially of those collected at the Indian and Colonial Exhibition. He was an earnest advocate of scientific and technical education, and his kindness and readiness to impart information to others will make his death felt as a personal loss by many outside the circle of his immediate friends. He died at Bristol on Sunday, October 23rd.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

PATENTS.

Improvements in and relating to Apparatus for Expressing Liquids from Vegetable, Animal, or Mineral Substances. H. H. Lake, London. From La Société Anonyme du Compresseur Jourdan, Paris. Eng. Pat. 17,886, October 19, 1891.

See under XII., page 1017.

Improvements in Apparatus for Evaporating, Condensing, and the like. G. Y. Blair, Stockton-on-Tees. Eng. Pat. 20,125, November 19, 1891.

THIS patent refers to means for cleaning or changing the coils in evaporators or similar apparatus in which special coils are used enclosed within an upright vessel. The coils are placed around a common centre upon a revolving trunnion with arms through which the steam has free access to them, and they may be successively brought opposite a door or opening in the vessel when required for examination, cleansing, or removal.—B.

Improvements in Apparatus for Producing Cold in or Freezing Liquids. J. W. Bowley, London. Eng. Pat. 20,563, November 26, 1891.

IN this apparatus the vessel holding the freezing mixture is traversed by horizontal tubes through which the liquid or material for cooling is passed. Each tube is provided with a screw conveyor, which in revolving effects a rapid equalisation of temperature and acceleration of the process.—B.

* Any of these specifications may be obtained by post by remitting 5s.—the price now fixed for all specifications, postage included—to Sir Henry Reader Luck, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C.

Improvements in Thermometers. J. Dawson, Rochdale.
Eng. Pat. 21,157, December 4, 1891.

THE object of this invention is to provide a thermometer better adapted to withstand the rough usage and sudden changes of temperature to which they are liable to be exposed in dye-vats, &c. A collar is formed on the glass thermometer tube about one-third of the length from the top; the lower part of the tube is mounted in a metal casing by means of india-rubber washers; the upper part of the tube is fitted with a scale in an enlarged continuation of the metal casing, and an index finger is provided, which may be adjusted from the outside by means of a key fitting the end of a traversing screw.—J. C. C.

Improvements in Bottles or Holders for the Storage and Conveyance of Quicksilver, Gas, and other Fluids under High Pressure, and in the Method of Manufacture thereof. J. Brotherton, Wolverhampton, and W. Griffith, Sheffield. Eng. Pat. 21,507, December 9, 1891.

THIS invention relates to an improved method for securing the tops and bottoms to metallic holders or bottles used for

storing quicksilver or gases under high pressure. The ends of the cylindrical tubes forming the holder are drawn or forged into a conical shape so as to leave the ends into which the plugs are fastened of smaller diameter than that of the tubes. These holes are slightly bell-mouthed and sometimes beaded, and the end pieces made to fit, when they are welded together with the aid of tools of special shape.—B.

Improvements in Filtering Apparatus. P. A. Newton, London. From M. Weigel, Tetschen, Bohemia, Austria.
Eng. Pat. 21,714, December 11, 1891.

IN this apparatus the filtration is effected by means of fibrous material, or cellulose, which at the commencement is added to the water to be filtered, and is deposited on the side surfaces, so as to form filtering beds for the remainder of the liquid. The accompanying illustrations show the arrangement recommended.

IN the tank *a* are placed filtering frames *s* covered on both sides with wire gauze and fitted with perforated drainage tubes *t*, which communicate with the exit chamber *c*.

Fig. 1.

Fig. 3.

Fig. 2.

Fig. 4.

IMPROVEMENTS IN FILTERING APPARATUS.

Here there is an outlet tube *l*, fitted with sluice *k* and an outlet with plug *m*. The inlet chamber *b* is fitted with sluices *q* and *r* for regulation of the supply, and with openings for cleaning. At starting, the outlet *m* is left open in order to allow turbid liquid to be drawn off separately, until the actual filtering surfaces have been formed, when the liquid commences to run clear and is allowed to leave through the pipe *l*.—B.

Improvements in Air Compressors. S. H. Johnson and C. H. Hutchinson, Stratford. Eng. Pat. 3, January 1, 1892.

IN order to avoid the waste spaces between the reciprocating piston of an air compressor and the cylinder covers when it reaches the end of the stroke, the patentees allow the piston to come in contact with the end covers. In order to accomplish this without danger of breakage they construct

the body of the piston in such a manner as to allow the end to yield on striking the covers, as will be seen from the accompanying illustration. They also use large gridiron

IMPROVEMENTS IN AIR COMPRESSORS.

valves of light construction, having a low lift, in order to secure a high piston speed, with little wear on the valves.—B.

Improvements in Stores or Apparatus for Drying Skins, Malt, Phosphates, and Animal, Vegetable, and Mineral Products. A. Rübenkamp, Dortmund, Germany. Eng. Pat. 9992, May 26, 1892.

THE object of this invention is to avoid the great loss of heat from drying stoves when the products of combustion and the hot air are allowed to escape directly into the atmosphere, and to effect a gradual cooling of the goods under treatment.

The air for drying the goods passes through pipes or channels arranged in a closed furnace chamber. The air thus heated having been led through the drying chamber is brought back to the closed furnace, where it effects combustion of the fuel. The products of combustion are not conducted directly to the chimney, but are passed through the heating tubes of a second apparatus, to which it gives up portion of its heat. When the goods in the first chamber are dry they are allowed to cool slowly by diverting the heat to the second chamber, which is then brought into use. The drying chambers may be arranged in series and the air heated by a central furnace. One advantage of the apparatus is that the noxious gases, given off by the goods under treatment, are burnt in the furnace, and thus rendered innocuous.—D. A. S.

Improvements in Apparatus for Grinding, Crushing, Pulverising, or Disintegrating. J. U. Askham, Shetfield. Eng. Pat. 14,663, August 13, 1892.

THE described improvements are in grinding mills of the roller centrifugal class of machine. The specification describes detachable wearing surfaces for the drivers, cylindrical grinding paths formed in parts, and arrangements of feed-hoppers, to avoid their removal during repairs to the machine.—J. C. C.

Improvements in Steam Superheating Apparatus and Appliances in connection therewith. L. Uhler and H. Cadische, Bâle, Switzerland. Eng. Pat. 15,308, August 25, 1892.

THIS specification proposes certain improvements in the apparatus described in Eng. Pat. 12,372, 1890. The tubes are placed horizontally instead of vertically, and by a series of tubes or bars are protected against excessive heating; the fire may therefore be brought nearer, and a better utilisation of heat effected. Besides other improvements, an apparatus is described for drying and purifying the steam before entering the superheater.—J. C. C.

Improvements in Furnaces. J. Sargent, Rochester, U.S.A. Eng. Pat. 15,514, August 30, 1892.

THIS patent relates to furnaces in which, when the doors are opened to apply fresh fuel, a jet of steam is turned on over the fire and air is admitted over the fire to produce

combustion of the smoke. The improvement consists in the application of a time mechanism, whereby steam is turned on; a supplementary furnace door is opened, and the time mechanism wound up by opening the main door of the furnace. The time mechanism is provided with suitable connections for turning off the steam and for closing the supplementary door at the end of a given period.—F. S. K.

Self-Acting Apparatus for Raising Liquid by Compressed Air or other Elastic Fluid under Pressure. P. Kestner, Lille, France. Eng. Pat. 15,648, August 31, 1892.

B is a vessel supplying the liquid to be raised to the cistern C by means of compressed air supplied by the pipe T_3 . On the vertical limb of this pipe, within the vessel A, is a float X, which closes the pipe T_3 , unless it is buoyed up by liquid, and when raised by the liquid which enters the vessel A closes the inlet from the pipe T_2 . The action is as follows: When the vessel A is being filled by

SELF-ACTING APPARATUS FOR RAISING LIQUID BY COMPRESSED AIR.

liquid from the pipe T_2 , air escapes by T_1 until the float X closing T_1 and T_2 opens T_3 . Compressed air now enters A, and forces the liquid up the pipe T until A is emptied of liquid, and air escapes up T, relieving the pressure in A, whereupon the float X drops, closing T_3 and opening T_1 and T_2 ; and the action is repeated.—J. C. C.

An Improved Universal Thermometer. E. Edwards, London. From H. Hartl, Reichenberg, Bohemia. Eng. Pat. 12,553, July 7, 1892.

THE object of this invention is to provide means by which—

1. The temperature indicated by the thermometer may be read off directly.
2. This indication may be registered at a distant room or station.
3. The thermometer may be adjusted for any temperature so that a rise or fall of the mercury of 1° — 2° C. also may be indicated at a distant station.

The details of the invention cannot be described without reference to the drawings.—J. C. C.

II.—FUEL, GAS, AND LIGHT.

Calorific Power of Coal, and Formula by which it is Calculated. Scheurer-Kestner. Bull. Soc. Chim. 7—8, 1892, 475—480.

THE experiments of the author and Meunier-Dollfus have clearly demonstrated that it is impossible to determine accurately the calorific power of a combustible mineral, except by experiment, and that any value, calculated from the composition of the substance, is in every case uncertain. In the present paper the author controverts a statement made by Bunte in Schilling's Journal, that the calorific power of a coal can be calculated with a sufficient degree of accuracy by employing the old formula of Dulong; he gives specific instances, showing that the calculated value is sometimes as much as 6 per cent. higher or lower than the actual value determined experimentally. He also describes experiments which prove that Berthier's method of determining the calorific value of a coal is most inaccurate.—F. S. K.

On the Formation of Petroleum. Engler. Austrian Society of Chemical Industry, Meeting of June 4, 1892. Chem. Zeit. 16, 1892, 843—844.

THERE have been a number of theories put forward to account for the formation of petroleum; Mendelejeff considers it to be formed by the decomposition of a carbide of iron by steam, ferric oxide and a hydrocarbon being produced; Sokoloff, by a combination of carbon and hydrogen; Ross by the reaction of sulphuretted hydrogen and calcium carbonate; Daubrée by the decomposition of vegetable matter. The author is inclined to consider it produced by the decomposition of animal substances; it is possible to obtain petroleum by distilling animal matter under pressure. (This Journal, 1891, 753, 979, and 980).—A. L. S.

The Combustion of Gaseous Mixtures. P. Askenasy and V. Meyer. Annalen, 269, 49—72.

See under XXIII., page 1039.

The Behaviour of Ethylene on Explosion with less than its own Volume of Oxygen. B. Lean and W. A. Bone. Proc. Chem. Soc. 1892, 115, 144.

AFTER giving a brief account of previous observations, the authors describe a series of experiments in which mixtures of ethylene with its own or a less volume of oxygen were fired in a leaden coil. Their results are in agreement with those of Dalton, Kersten, and E. von Meyer, and show that, when fired with about its own volume of oxygen, ethylene yields mainly carbonic oxide and hydrogen as the final result; but they have also observed that methane, acetylene, and carbon are produced.

The following are the tabulated results of the analyses :—

Composition of Mixture.	C.	D.	E.	F.	G.
Ethylene	56.03	51.18	49.77	48.64	49.41
Oxygen	39.16	41.52	45.81	45.84	47.69
Nitrogen	4.51	4.30	4.42	5.52	2.90

Composition of Product.	C.	D.	E.	F.	G.
Unsaturated hydrocarbons ..	5.53	3.77	2.78	2.14	..
Methane	5.96	3.77	2.52	2.55	1.01
Carbon dioxide	1.63	2.80	1.24	0.94	0.33
„ monoxide	38.85	44.84	47.79	46.53	49.11
Hydrogen	43.30	41.72	43.32	45.35	48.78
Nitrogen	5.16	3.10	2.35	2.49	1.01

Incidentally it is shown that oxygen is appreciably absorbed by fuming sulphuric acid, but that neither strong potash nor alkaline pyrogallol solution appreciably affects ethylene.

PATENTS.

Improvements in or Relating to the Manufacture of Coke.

Sir G. Elliot, London, and J. MacGowan, jun., Stoke-on-Trent, Staffordshire. Eng. Pat. 19,758, November 14, 1891.

By employing the apparatus and method of coking described in this patent it is claimed that the percentage of sulphur in coke can be reduced and the commercial value of the fuel increased; if desired the sulphur may be recovered.

Any convenient form of coke oven may be employed. The fumes from the chimney at the top are first carried to the end of the furnace, and are then caused to pass through a series of flues underneath the floor of the oven so that their heat may be utilised; they then pass away into the main flue. The flues underneath the floor of one oven are connected by bye-pass flues to those of the other ovens, so that the waste heat can be utilised for maintaining the temperature when necessary.

“In the lower portion of the oven is a pipe connected with any suitable form of exhaust fan or suction apparatus, by which the sulphur and heavier gases, which would collect in the lower part of the oven and would not be removed by the upper flue, can be drawn off. This drawing off we prefer only to effect at the termination of the coking process, and, if desired, after the admission of steam and water to the contents of the oven.”

In the lower corner of the oven a number of tiles are arranged obliquely at slight intervals apart, “so that the heavy sulphurous fumes may readily have access to the pipe provided for their removal at or below the level of the floor.”—F. S. K.

Improvements in Feeding Fuel to Gas Producers, and in the Generation of Combustible Gas. J. Hargreaves, Widnes. Eng. Pat. 20,573, November 26, 1891.

THE fuel is fed into the producer from the bottom upwards, at a point preferably above and in front of the nozzle, through which the air and steam are supplied, in such a manner that the fuel piles itself up into the body of the producer. The inventor claims also the combination of this system with the supply of measured quantities of air and fuel, and with steam to gas producers, so as to obtain a desired quality of evolved gas.

Any suitable feed and measuring appliances for solid fuel and air may be used.—D. A. S.

Improvements in Coke Ovens to Facilitate the Cooling of the Coke before Drawing. C. E. Bell, Durham. Eng. Pat. 22,106, December 17, 1891.

THE usual method of cooling coke prior to its withdrawal from the oven is to spray water over it from the top by means of a long perforated pipe coupled to a flexible water supply main and worked by hand. In this patent the method of cooling is improved by making use of a water pipe which is fixed within the arched radial passage of the oven, or introduced into the opening at the top of the domed roof of the oven: this pipe is provided with a rose or perforated end so that after opening the oven and turning on the water the spray falls over the whole upper surface of the coke.—F. S. K.

Improvements in Supplying Heated Air to Steam Generating and other Furnaces. G. W. Hawksley, Sheffield. Eng. Pat. 22,208, December 19, 1891.

THE object of this invention is to supply a stream of heated air in such a manner as to cause the more perfect combustion of the unburnt gases, and so reduce the production of smoke and increase the draught.

An air tube or conduit is fixed near the crown of the flue and runs longitudinally with it over the fire-box, terminating in a nozzle or spreader at some little distance from the bridge. The front end of the tube is conveniently formed to receive a small jet of steam or compressed air. When the jet is turned on a current of steam and air, or of air alone, is forced along the hot pipe and expelled from the nozzle in a sheet across the heated gases.—D. A. S.

Improvements in Artificial Fuel. C. Winter, Tottenham. Eng. Pat. 16,322, September 12, 1892.

IN the manufacture of this artificial fuel any kind of refuse vegetable matter is used, in combination with lime or cement, and refuse cocoa-nut fibre or refuse tan, and coal or coke dust. The selected ingredients, when intimately mixed together, form a plastic compound, which is pressed into blocks and allowed to set hard. The inventor claims that one ton of these blocks will give off, during combustion, an amount of heat equal to that emitted by a ton of the best household coal.—D. A. S.

Improvements in Apparatus for Simultaneously Burning both the Light and Heavy Portions of Vaporisable Oils at one Burner. W. P. Thompson, Liverpool. From G. H. Harvey, G. F. Perrenoud, J. Getty, and G. D. Bayard, New York, U.S.A. Eng. Pat. 16,359, September 13, 1892.

IN the apparatus pipes lead from the top and bottom of the carburettor to the burner. Air, which may be heated before entering or when passing through the carburettor, is forced in at sufficient pressure to maintain a flow of heavy oil to the burner from the bottom pipe, while a supply of carburetted air passes from the top, both of which can be regulated by suitable valves.—D. A. S.

Improvements in the Manufacture of Gas. R. M. Bidelman, Adrian, Michigan, U.S.A. Eng. Pat. 17,262, September 27, 1892.

IN this process air is passed through a liquid hydrocarbon, which has already been deprived of all vapours which condense at the ordinary temperatures of a gas main, and the resulting gas is used for heating purposes, or with Welsbach burners for the production of light.

The inventor recommends the use of a distillate of petroleum oil of specific gravity approximately 0.698, from which all the more readily condensable hydrocarbons have been removed.

The liquid hydrocarbon employed is forced from a suitable reservoir into the generating receptacle. This receptacle consists of a cylindrical metallic shell capable

of resisting considerable internal pressure. A few inches above the bottom there is a perforated false bottom, upon which rests a packed body of absorptive solid porous material such as wood charcoal or its equivalent. These receptacles are connected in series by pipes leading from the top of one receptacle to below the perforated false bottom of the next. The above-mentioned distillate is forced into the receptacles until the space below the perforated diaphragms is filled, and the liquid rises well up into the body of the charcoal. Compressed air is then forced through the series to the point of storage or use. Analyses show that the gas produced contains about 3 per cent. of fixed hydrocarbon gases, of which marsh-gas is the principal constituent, the other constituents being olefiant gas and other heavy hydrocarbons intermixed with air.—D. A. S.

Improvements in the Combustion of Carbonaceous Fuel. E. A. Ebb, Appleton, U.S.A. Eng. Pat. 12,762, July 12, 1892.

IN the combustion of carbonaceous fuel the formation of carbon dioxide, which is a non-supporter of combustion, has a tendency to check the process of combustion while being drawn up through the fuel.

The object of this patent is to remove the carbon dioxide by taking advantage of the fact that this gas is specifically heavier than air. This is done by introducing a pipe into the centre of the ash-pit and connecting the pipe with an exhaust fan. As, when bituminous coal, or coal-dust is employed its caking obstructs the passage of the carbon dioxide cubical perforated blocks of iron or short tubes of iron are mixed with the fuel in any quantity desired; these afford a free passage to the gas so that it may be drawn off from below. Steam is injected into the fuel chamber whenever the iron blocks are red hot.

The patentee claims: "The improvement herein described in the combustion of carbonaceous fuel, the same consisting in running off the generated carbonic acid gas by its own gravity, assisted by an exhaust fan or other exhaust pump device, and further assisted by feeding the fuel mixed with perforated iron cubes, or other forms of perforated iron, and further assisted by injecting steam in the fuel chamber."

—F. S. K.

IV.—COLOURING MATTERS AND DYES.

Indothymol: Preparation of Thymoquinone. P. H. Bayrac. Bull. Soc. Chim. 7-8, 1892, 97-99.

Indothymol—

the indophenol of thymol, is formed on mixing a dilute solution of *p*-amidodimethylaniline with a dilute alkaline solution of thymol, adding potassium bichromate and faintly acidifying with acetic acid. It is purified by washing successively with water and a small quantity of cold alcohol, and crystallising from alcohol, being thus obtained in long violet-green dichroic needles, which melt at 69.5° C. and are slightly sublimable. It is insoluble in water and alkalis; soluble in alcohol with a fine blue colour, and in acetic acid with a green one; it is reduced by zinc and acetic acid to its easily oxidisable leuco-derivative; is unacted upon by aqueous solutions of alkalis, but is decomposed by mineral acids quantitatively into dimethylaniline, ammonia, and thymoquinone. This reaction furnishes a ready method of preparation of the last-named compound, which is obtained with difficulty by the methods in general use:—The indothymol is decomposed by gently heating for a few minutes with 10 times its weight of dilute (1:10) sulphuric acid, and the solution cooled. The

thymoquinone is then extracted with ether, the solution evaporated and the residue dissolved in a mixture of ether and alcohol, and filtered. On evaporation pure thymoquinone is obtained.—E. B.

Some Derivatives of Chrysaniline. A. Trillat and De Raekowski. Bull. Soc. Chim. 7—8, 1892, 257—259.

Tetrazophenylacridine—

is formed (the sodium salt of the naphthol disulphonic acid) by the action of nitrous acid on a cold dilute solution of diamidophenylacridine (chrysaniline) which is obtained, probably along with higher homologues, by precipitation with sodium carbonate from a dilute solution of phosphine. It combines readily (although perhaps in two stages like other tetrazo compounds) with phenols and amido compounds; thus, with the sodium salt of naphthol disulphonic acid R it yields a compound which in the dry state appears green, but when in solution has a splendid red colour. Salt G similarly yields a pink dye (see above formula). These two compounds dye silk very well, but give only poor colours on cotton and wool. Alkyl derivatives of chrysaniline are produced on heating it in alcoholic solution with alkyl iodides. The dibenzyl derivative is obtained by the action of benzyl chloride in the form of a sparingly soluble brown paste which appears to be microcrystallisable. It dyes silk, cotton, and wool dull red, the methyl and ethyl derivatives dyeing a similar shade. None of these derivatives possesses much technical value.—E. B.

The Action of Hypochlorous Acid on β -Naphthaquinone.

E. Bamberger and M. Kitchelt. Ber. 1892, 25, 133—136 and 888—898.

β -NAPHTHAQUINONE is converted by hypochlorous acid, according to the conditions obtaining, either into a colouring-matter isomeric with naphthazarin, or into a mixture of acids, amongst which phthalic acid and the δ -lactone of α -carboxyphenylglyceric acid have been recognised.

The colouring matter is formed by adding 2.5 to 5 grms. of the quinone, in the state of very fine powder, to a solution of hypochlorous acid, prepared by grinding 35 grms. of bleaching-powder with 135 of water, adding a solution of 26 grms. of potassium carbonate in 40 of water, filtering, adding 20 grms. of boric acid to the filtrate, and, after an hour's rest, filtering from the potassium borate which has crystallised out. Considerable heat is evolved when the quinone is added. The action is assisted by 8 or 10 minutes' agitation, after which the quinone will have dissolved with an olive-brown colour, which rapidly changes to orange. As soon as this change has taken place, concentrated hydrochloric acid is added and the solution is heated until its colour suddenly turns dark red, when the heating must be discontinued. The solution is now allowed to stand for several hours to enable the colouring matter to crystallise out. Some boric acid simultaneously separates, but is easily removed by washing the crystals with hot water. The mother-liquor still contains a not inconsiderable amount of the colouring matter, which is precipitated by copper acetate and liberated in an almost pure condition from the dark-blue copper compound thus formed, by pouring hydrochloric acid over it. Both quantities of the colouring matters so obtained contain traces of a second one, probably a monohydroxynaphthaquinone, which dissolves in alkalis with a red colour. It is removed by

crystallising from acetone or, less satisfactorily, by subliming. The yield of the chief colouring matter amounts to 45—50 per cent. of the β -naphthaquinone employed. This colouring matter, on account of its close resemblance, both chemically and physically, to naphthazarin has been named *Isonaphthazarin*. It crystallises in splendid orange-red plates with a green surface-lustre, and is obtained by sublimation in needles of a metallic lustre, which differ from those of naphthazarin by their paler appearance. It melts at 276° ; is sparingly soluble in hot water, and very sparingly in cold, but still appreciably more so than its isomeride. Acetone dissolves it readily, chloroform and alcohol with moderate ease, and ether and benzene very slightly; each with an orange colour. Concentrated sulphuric acid dissolves it with a dark red colour. Sodium and potassium hydrates dissolve it easily with a blue colour; carbonated alkalis and ammonia with a violet-red. Its acidity is greater than that of naphthazarin: for while a solution of the latter is unaffected by the addition of sodium acetate, one of isonaphthazarin is coloured red-violet (= the red-orange of the free dyestuff + the blue of its sodium compound), the acetic acid being partly displaced by it. Its aqueous solution, also, reddens litmus strongly. The alkaline solutions are decolorised by a month's exposure to light. The sodium compound is precipitated by common salt from its aqueous solution in voluminous indigo-blue flocks. Isonaphthazarin yields coloured precipitates with salts of the following metals: copper, lead, cadmium, and nickel, dark-blue; zinc and barium, pale-blue; mercury and cobalt, green-blue. It also dyes very well on metallic hydrate mordants, giving on chrome, for instance, a beautiful purple-grey colour. Its want of fastness to light, however, will stand in the way of its technical application. The above detailed properties of the substance correspond with a compound containing hydroxyl groups in close proximity to a quinone complex, thus—

Its analysis accords with this view. The formation of this compound probably takes place in the following phases:—

The lactone compound is produced by the action of sodium hypochlorite on β -naphthaquinone.—E. B.

Oxidation Compounds of Amidonaphthol Sulphonic Acids.

F. Reverdin and C. de la Harpe. Ber. 1892, 25, 1400—1409.

I.—DERIVATIVES OF α -NAPHTHOL.

1:2:4 (=OH:NH $_2$:SO $_3$ H)—Amidonaphthol sulphonic acid yields a purple dye when heated in sodium carbonate solution in the presence of air. The alkaline solution has at first a green tint, but gradually turns brown and deposits a purple powder which is filtered off. A compound which dyes wool red-brown remains in the filtrate. The latter is produced in larger amount when the free sulphonic acid is oxidised, and is probably, therefore, a sulphonic acid of α -naphthaquinone (this Journal, 1892, 155). The purple compound is sparingly soluble in cold water, but more readily in hot, and easily in alkalis. It is precipitated by acids from its alkaline solutions in chocolate flocks, which after some time becomes green and crystalline. Sulphuric acid dissolves it with an olive colour. It dyes wool from an acid bath purple to black shades according to the proportion employed, and dyes cotton which is mordanted with

metallic oxides, the shades produced being in both cases very fast. A compound possessing the same properties is obtained by sulphonating imido-oxynaphthalene, the oxidation product of 1:2 amidonaphthol. From this it would appear that the purple dye is an imido-oxynaphthalene sulphonic acid of the constitution—

A body which closely resembles this dye as regards its behaviour in wool dyeing, but which does not dye so well on mordanted cotton, is produced by adding sodium acetate to a dilute solution of the above amidonaphthol sulphonic acid, and allowing to stand a considerable time in the cold, or more rapidly by treating with a current of air.

1:4:2-Amidonaphthol sulphonic acid, when heated in sodium carbonate solution, is coloured golden-brown by the air; in sodium acetate solution it is coloured red-purple. The body produced cannot be precipitated with either common salt or acids, and dyes wool in an acid bath a worthless yellow-brown.

Two amidonaphthol sulphonic acids are obtained on diazotising Witt's 1:5-naphthylamine sulphonic acid, boiling with dilute acid, combining with diazobenzene chloride and reducing. The azo-compounds were separated by taking advantage of the difference in their solubilities. The more soluble compound which was of a yellowish colour, gave on reduction a sparingly soluble product, whose solution in sodium carbonate was oxidised similarly to the 1:2:4-amidonaphthol sulphonic acid, while the little soluble reduction-product of the other compound oxidised into a brown dye of no value, thus resembling the 1:4:2-acid. The first reduction-product would, therefore, seem to be the 1:2:5-, and the second the 1:4:5-amidonaphthol sulphonic acid.

1:4:8-Amidonaphthol sulphonic acid in sodium carbonate or ammonia solution, becomes brown on exposure to air; in sodium acetate solution it becomes red-brown and eventually purple. The compound formed gives a brown colour on wool but is of no technical value.

1:4:2:7-Amidonaphthol disulphonic acid is converted by the atmospheric oxidation of its sodium carbonate solution into a red purple dye, which is precipitable by common salt, and gives a fairly-bright purple on wool in an acid bath, but dyes imperfectly on cotton mordanted with metallic oxides, yielding greenish-olive shades.

II.—DERIVATIVES OF β -NAPHTHOL.

2:1:6-Amidonaphthol sulphonic acid (*Eikonogen*) becomes coloured olive-green when exposed to the air in sodium carbonate solution. The addition of common salt produces a voluminous precipitate of a compound which dissolves in water with a green colour, but is changed to red by acidifying. This compound dyes red-purple on unmordanted wool, green on chrome-mordanted wool, and grey or grey-olive on mordanted cotton.

2:1:8-Amidonaphthol sulphonic acid yields a similar product which does not, however, dye mordanted cotton so well as the preceding compound.

2:1:5-Amidonaphthol sulphonic, and 2:1:3:6-amidonaphthol disulphonic acids give brown oxidation-products of no value as dyes. The 2:1:6:8-disulphonic acid (from orange G) gives a small quantity of a dye resembling that obtained from the 2:1:8-acid, its formation being probably due to the presence of this acid.—E. B.

at a low temperature β -naphthylamine nitrate is converted by sulphuric acid essentially into a mixture of two new nitronaphthylamines, namely, the 2:5- and 2:8-derivatives.

The nitration is effected by gradually adding finely-powdered β -naphthylamine, dried at about 100° C. (a higher temperature causes decomposition), to 10 parts of concentrated sulphuric acid, at a temperature not exceeding 5°. The low temperature is important, as considerable quantities of resinous matters are formed if it be allowed to rise. Thus, in an operation conducted between -22° and -12° only 10 per cent. (of the nitrate employed) of resinous matters was formed, while between -11° and +2°, 18 per cent., between -5° and +6°, 26 per cent., between -7° and +10°, 31 per cent., and between 0° and 11° C. 42 per cent. were produced. The resinous matters were removed by diluting the sulphuric acid solution with 6 to 8 volumes of water and filtering. On cooling, the greater part of the nitro-products crystallised out as a brown-yellow mass, a further small quantity being obtained on neutralising the mother-liquor. From these salts the nitro-bases were liberated by ammonia and dried on the water-bath, a mean yield of 60 per cent. of the theoretical being obtained. The dried mass was then separated by fractional crystallisation from benzene or alcohol into a sparingly-soluble compound, recognised as the 2:5-derivative, and a more soluble 2:8-compound, which is produced in smaller amount. The latter body is best isolated by acetylating the mixture of bases and repeatedly crystallising from a large volume of alcohol until the crystals obtained are uniform and melt at 195.5°; the free base being then obtained in the usual manner. The alcoholic mother-liquors contain the acetyl compounds of other bases (of lower melting point) than the above, which have not yet been identified.

2:5-nitro- β -naphthylamine forms beautiful red needles, melting at 143°, which dissolve readily in hot alcohol (with dark red colour) and in benzene (with pale yellow) and acetic acid, sparingly in hot water, and scarcely at all in cold water and light petroleum. The hydrochloride of the base dissolves easily in hot water and crystallises in nearly colourless needles. The sulphate is sparingly soluble, and, when slowly crystallised, forms pale yellow laminae. Both salts undergo partial dissociation when heated with a large quantity of water or alcohol. The acetyl-derivative crystallises in stellate aggregates of melting point 185.5°; the benzoyl-derivative in needles, melting at 181.5°. Nitrous acid converts the amido compound into 2:5-nitrodiazonaphthalene. This is readily soluble in water, and combines with naphtholsulphonic acids, forming brownish-red to purple dyes.

2:5-nitro- β -naphthol is prepared by boiling the aqueous solution of the last-mentioned compound with a small quantity of urea until the evolution of nitrogen has ceased. After filtering off the resinous matters which are simultaneously formed, and cooling, it crystallises out as a pale yellow acicular mass. It melts at 147°, and is sparingly soluble in cold water, but readily so in hot, and dissolves readily in dilute alkaline solutions and in the customary organic solvents. Its potassium salt is precipitated by an excess of potash in red laminae.

2:5-amido- β -naphthol is formed on carefully reducing the nitro-compound with excess of a mixture of stannous chloride, tin, and hydrochloric acid. The stannous double salt which separates is conveniently decomposed by dissolving in the minimum quantity of hot water and adding concentrated hydrochloric acid, the hydrochloride of the amido-compound being precipitated in an almost pure state. On decomposing this precipitate with sodium bicarbonate and extracting from the filtered aqueous solution, the free base is obtained as a white, crystalline mass, easily soluble in acids, alkalis, and organic solvents. When exposed to the air, it suffers oxidation and darkens.

2:5-naphthylenediamine is obtained by the reduction of the above nitronaphthylamine. It is easily soluble in hot water, alcohol, benzene, and acetic acid, sparingly so in cold water and ether, and crystallises in short, white needles, of melting point 77.5°, which darken on exposure to air. Its aqueous solution shows a blue fluorescence, and is coloured purple by ferric chloride or bleaching powder. When heated on the water-bath with fuming sulphuric acid it

The Nitration of β -Naphthylamine. P. Friedländer and St. Szymanski. Ber. 25, 1892, 2076—2083.

THE authors undertook this research in consequence of a statement by Hirsch (Ger. Pat. 57,491) that the nitration of β -nitronaphthylamine followed a different course from that supposed by Levinstein (Ger. Pat. 30,889). They find that

yields a sparingly-soluble sulphonic acid. This description of the properties of 2:5-naphthylenediamine does not agree with that given by Ewer and Pick (Ger. Pat. 45,788), who considered they obtained the body in question (which they stated to be uncrystallisable) by heating 1:6 (= 2:5)-dihydroxynaphthalene with ammonia under pressure. Also the assertion that the tetrazo-derivatives of this naphthylenediamine dye unmordanted cotton is found to be incorrect (this Journal, 1889, 278).

2:5-dichloronaphthalene. The constitution of the above compounds was proved by converting the diamido-compound into the corresponding dichlor-derivative by diazotising and treating with copper powder (this Journal, 1890, 923). The dichloro-compound, which was isolated by distillation with steam, melted at 48° and possessed the properties ascribed to the 2:5-compound by Erdmann and Kirchhoff (Ann. 247, 379).

2:8-nitro- β -naphthylamine, produced as above described, forms red needles melting at 103.5°, and soluble with difficulty in hot water (in which the compound melts), and very sparingly in light petroleum, but easily in other organic menstrua. Its sulphate and hydrochloride are rather less soluble than the corresponding salts of the 2:5 compound, and like these are partially dissociated by heating in dilute aqueous or alcoholic solution. Its acetyl compound crystallises in long yellow needles melting at 195.5°. It is converted by the diazo reaction into 2:8-nitro- β -naphthol, a considerably better yield of this substance than of its isomeride from the 2:5-nitronaphthylamine being obtained. This compound crystallises in dark red needles which melt at 142°, and is easily soluble in alcohol, but with difficulty in water. It dissolves in alkalis with a dark red colour, and its potassium salt is precipitated in red needles on the addition of a large excess of potash.

2:8-amido- β -naphthol was prepared and isolated in the same manner as its above-described isomeride. It crystallises in small white needles which darken on exposure to air and decompose, without melting, at 212°–218°, and is soluble in acids and alkalis, as well as in water, alcohol, and ether.

2:8-naphthylenediamine is formed on allowing an alcoholic solution of the corresponding nitronaphthylamine to flow gradually into an excess of a mixture of stannous chloride, hydrochloric acid, and tin. It is easily soluble in acetic acid, alcohol, and benzene, less so in water, and very slightly so in ether and light petroleum, and crystallises from benzene in white plates, but from water in feathery clusters of needles, of melting point 117.5°. The surfaces of the crystals rapidly darken when exposed to the air. The aqueous solution of this compound shows a faint fluorescence, and is coloured violet by ferric chloride. Its tetrazo-derivative combines with naphthol-sulphonic acids, forming purple-brown dyes, and is converted by copper powder and hydrochloric acid into 2:8-dichloronaphthalene (Erdmann and Marchand, *loc. cit.*), of melting point 61°.

—E. B.

Methoxyamido-1:3-Dimethylbenzene and some of its Derivatives. W. R. Hodgkinson and L. Limpach. Proc. Chem. Soc. 1892, 115, 166.

HAVING devised a method of separating 1:2:4-metaxylyline from paraxylyline, &c., with which it is mixed in commercial xylidine, the authors have had the opportunity of preparing 1:2:4-metaxylylenol in large quantity. An almost theoretical yield of this phenol was obtained by diazotising a solution containing only 5 per cent. of the xylidine sulphate and then steam distilling; the product did not solidify even at -20°; but a considerable quantity was caused to crystallise by adding some solid obtained by cooling a small portion by means of carbon dioxide and ether. The presence of a trace of water was found to prevent crystallisation. On nitration, metaxylylenol yields almost the theoretical amount of a nitroxylylenol in which the NO₂ group is contiguous to the hydroxyl. The authors have prepared the corresponding amido- and hydroxy-xyleneols and their methylated derivatives (dimethylanisoils); they also describe a quinaldine derivative, formed by condensation from the methoxy-amidoxylylene and ethylic aceto-acetate.—W. S.

PATENTS.

Improvements in the Manufacture of Alpha-Naphthol Sulpho Acids and Diary Naphthalene Sulpho Acids, and of Dyestuffs therefrom. B. Willeox, London. From "The Farben fabriken vormals F. Bayer & Co.," Elberfeld, Germany. Eng. Pat. 3397, March 4, 1890. (Second Edition.)

The specification describes the preparation of two new α -naphthol disulphonic acids, a new trisulphonic acid and new dihydroxy naphthalene sulphonic acids therefrom. The following methods are given for the formation of these new products. A certain weight of α -naphthol sulphonic acid (OH: SO₃H = 1: 5) is dissolved in three times its weight of sulphuric acid of 66° B., the temperature is slowly raised to 90° C., on the water-bath and kept at this temperature until a change in the fluorescence shows that the sulphonation is complete, when the melt is limed and converted into the sodium salt which crystallises in spikes from a concentrated solution. This α -naphthol disulphonic acid differs from those described in Ger. Pat. 40,571 and 45,776 as it does not give a nitroso compound. Other sulphonating agents may be employed such as sulphuric acid monohydrate or monochlorhydrin. When α -naphthol sulphonic acid (OH: SO₃H = 1: 4) is dissolved in three times its weight of fuming sulphuric acid and slowly raised to the temperature of a water-bath, the mass stiffens at about 75° C., forming naphthyl sulphuric acid, and at about 90° the melt is in the form of a thin clear liquid. It is converted in the usual way into the sodium salt which precipitates in the form of jelly. This α -naphthol disulphonic acid only combines with difficulty with diazo compounds. The new α -naphthol trisulphonic acid is obtained by sulphonating the naphthosultone or naphthol mono- or disulphonic acid S described in Ger. Pat. 40,571, or from the naphthosultone monosulphonic acid. Any one of these acids is mixed with 4-5 times its weight of fuming sulphuric acid containing 25 per cent. of anhydride and allowed to stand at the ordinary temperature until a sample ceases to form a colouring matter with diazo compounds, which is generally the case after about twelve hours. At higher temperatures the sulphonation is completed more rapidly, but not at temperatures above 100° C., or when acid containing more anhydride is used. The melt is converted into the sodium salt and precipitated by adding hydrochloric acid and salt to the hot concentrated liquor, when it forms a heavy sandy powder. A characteristic property of the new acid is that it does not combine with diazo compounds. The neutral sodium salt dissolves easily in water with a green fluorescence. Nitric acid forms a nitro-naphthol sulphonic acid. By fusion with caustic alkalis at high temperatures all the above-mentioned acids are converted into new dihydroxynaphthalene sulphonic acids. The new α -naphthol disulphonic acids are fused with three parts of caustic soda at about 250° C., until a sample shows no fluorescence and smells strongly of sulphurous acid when acidulated. The α -naphthol disulphonic acid obtained from the 1:5 α -naphthol monosulphonic acid gives a dihydroxynaphthalene monosulphonic acid, the sodium salt of which crystallises in thin shining plates containing water from solutions saturated with salt. Ferric chloride gives an unstable blue-green solution and chloride of lime produces a reddish brown colour which does not change on adding an excess. The α -naphthol disulphonic acid from the 1:4 α -naphthol monosulphonic acid yields a dihydroxynaphthalene monosulphonic acid of which the sodium salt crystallises from acid solutions saturated with salt in fine white needles. Ferric chloride gives a permanent blue green solution and chloride of lime a bluish-red solution which turns yellow and then colourless. By heating the α -naphthol trisulphonic acid with concentrated soda-lye to 200° C. in an open vessel it is converted almost instantly into a new dihydroxy naphthalene disulphonic acid. The reaction is complete when a sample no longer fluoresces or when it gives a colour with diazo compounds. The melt is then dissolved in water and saturated with salt when the new dihydroxynaphthalene disulphonic acid crystallises out in white needles. The α -naphthol disulphonic acid obtained from the 1:5 α -naphthol monosulphonic acid and the dihydroxynaphthalene mono- and disulphonic acids above mentioned can all be employed in the manufacture of

colouring matters by combining them with diazo and tetrazo compounds. A variety of shades can be produced according to the particular amine employed. Blue to blue-black colouring matters, for instance, are obtained from *p*-phenylene diamine by diazotising acetyl-*p*-phenylene diamine, combining it with α -naphthylamine or α -amido- α -naphthol ether, rediazotising, combining with one of the above-mentioned dihydroxynaphthalene sulphonic acids splitting off the acetyl group, again diazotising and combining with a pbenol, amine or one of their derivatives.—T. A. L.

Improvements in the Manufacture and Production of Sulpho Acids and of Colouring Matters. B. Willcox, London. From "The Farbenfabriken vormals F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 19,062, November 4, 1891.

WHEN either methyl- or ethyl-benzylaniline is heated with monohydrated sulphuric acid or with fuming sulphuric acid of a moderate strength at a low temperature, it is converted into a mono-sulphonic acid, in which the sulphonic acid group is in the benzyl nucleus. By using fuming sulphuric acid of sufficient strength the bases are converted directly into disulphonic acids, one of the sulphonic acid groups having entered the phenyl nucleus in a meta position to the amido group so that the body has the following formula—

Where R stands for CH_3 or C_2H_5 .

Ten kilos. of ethylbenzylaniline are dissolved in 20 kilos. of cold fuming sulphuric acid containing 20 per cent. of SO_3 , and the solution mixed with 25 kilos. of fuming sulphuric acid containing 80 per cent. of SO_3 and heated to 60°C . The sulphonation is complete when a sample partially neutralised with sodium carbonate gives no precipitate on treating with an excess of sodium sulphate. The melt is then poured into water neutralised with lime, and the filtrate evaporated to a syrup which becomes solid on standing. The barium salt will crystallise from a concentrated aqueous solution. By decomposition with alkaline carbonates the corresponding alkaline salts are obtained, which can be precipitated by adding salt or potassium chloride. No precipitate is, however, produced by adding hydrochloric acid to the aqueous solution of the disulphonic acid, differing in this way from the monosulphonic acid. The position of the sulphonic acid group in the phenyl nucleus was determined by fusing the disulphonic acid with potash, when, after acidulating, an oil was obtained which gave a rhodamine on heating with phthalic anhydride and zinc chloride. These disulphonic acids condense with tetra-alkyldiamidobenzhydrols, forming leuco-compounds which on oxidation yield colouring matters. Two examples for the formation of blue to violet dyestuffs are given in the patent. 27 kilos. of tetramethyldiamidobenzhydrol are dissolved in 400 kilos. of dilute sulphuric acid (containing 5 per cent. of H_2SO_4), and after adding 40 kilos. of sodium methylbenzylaniline disulphonate the melt is heated on the water-bath until the condensation is complete, when, after neutralisation with sodium carbonate, the leuco-compound is salted out with sodium sulphate. This is then dissolved in 200 kilos. of 50 per cent. acetic acid and oxidised by adding 48 kilos. of a lead dioxide paste containing 50 per cent. of PbO_2 . The lead is precipitated with dilute sulphuric acid, and after filtering, the colouring matter is precipitated from the solution by adding sodium sulphate, when it separates in small brassy crystals very easily soluble in hot water, less so in cold, and dyes wool blue from an acid bath in a similar shade to that produced by "Cotton blue R." Another colouring matter is obtained by dissolving 27 kilos. of tetramethyldiamidobenzhydrol in 135 kilos. of dilute (10 per cent.) sulphuric acid and adding 20 kilos. of dimethylaniline-*m*-sulphonic acid dissolved in 80 litres of water. When the condensation is complete the solution is neutralised with sodium carbonate, and the sodium salt of the hexamethyl-*p*-leucaniline monosulphonic acid separates on cooling in characteristic lustrous scales. It is oxidised by the same quantities of acetic acid and PbO_2 given above, and the lead is

precipitated by adding 20 kilos. of sulphuric acid of 66°B . The filtrate from the lead sulphate is evaporated when the colouring matter separates. It possesses both basic and acid properties, and dyes cotton mordanted with tannic acid or wool from a neutral bath. All these dyestuffs are said to be valuable on account of their fastness to alkalis, and those which contain benzyl-groups dye wool from acid baths.—T. A. L.

Improvements in and relating to the Manufacture and Production of Azo-Dyes, and of Materials therefor. J. Y. Johnson, London. From the "Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 20,275, November 21, 1891. (Second Edition.)

IN Eng. Pat. 9676 of 1890 (this Journal, 1891, 538) 1·1' amidonaphthol monosulphonic acid is described, which combines with tetrazo compounds, giving however, dull colours. The benzoyl or acetyl derivatives of the acid give bright shades with tetrazo compounds; but in order to enable the dyestuff to be applied in a soap or soda bath the tetrazo compound must contain a sulphonic or carboxylic acid group, as otherwise the colouring matters will only dye from a bath containing a caustic alkali. In the present specification an isomeric 1·1' amido-naphthol sulphonic acid is described which yields colouring matters similar to the above, but does not require that the tetrazo compound shall contain an acid group, as the benzoyl or acetyl derivatives of the bodies produced from diazotised tolidine, for example, will dye cotton from an ordinary soap or soda bath. The starting point for the new acid is the naphthylamine disulphonic acid obtained by sulphonating that 1·1' naphthylamine sulphonic acid which forms a slightly soluble sodium salt. It is the so-called naphthylamine monosulphonic acid S of Eng. Pat. 15,775 of 1885 and of Ger Pat. 40,571. About 1 kilo. of the sodium naphthylamine disulphonate is mixed with 3 kilos. of caustic alkali and a little water, and heated from 200° — 230°C . until no increase in the quantity of the 1·1' hydroxynaphthylamine monosulphonic acid formed is observed. The melt is then allowed to cool, dissolved and acidified with dilute (3 per cent.) hydrochloric acid, boiled until all the SO_2 is given off, and filtered hot. On cooling, the new acid separates out in light grey crystals. The acid is slightly soluble in water or alcohol. The alkaline salts are readily soluble in water, and when alkaline have a bluish-green fluorescence. The substance combines with diazo and tetrazo compounds, which, however, are only dull colouring matters. By employing the benzoyl or acetyl derivatives of the new acid for combination with tetrazo compounds, bright and useful dyestuffs are obtained. About 10 kilos. of 1·1' hydroxynaphthylamine sulphonic acid and 7 kilos. of calcined soda are dissolved in 90 litres of water. After cooling to 5°C . 5·2 kilos. of benzoyl chloride are added and the mixture agitated below 10°C . for about one hour. The sodium salt of the benzoylated derivative is filtered, washed with brine, pressed and dried. A blue colouring matter is obtained from it by dissolving about 20 kilos. of the sodium salt and 15 kilos. of calcined soda in about 650 litres of water, and after adding 100 kilos. of ice, running in the tetrazodiphenyl chloride solution from 4·6 kilos. of benzidine, 16·5 kilos. of 30 per cent. hydrochloric acid, 250 litres of water, 50 kilos. of ice, and 3·5 kilos. of sodium nitrite. The mixture is then agitated for 24 hours at the ordinary temperature, after which it is boiled, precipitated with salt, filter-pressed and dried. The dyestuff forms a dark brown powder with a slight metallic sheen.—T. A. L.

The Manufacture and Production of New Derivatives of Alizarin and its Analogues. B. Willcox, London. From the "Farbenfabriken vormals F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 21,717, December 11, 1891.

THIS patent describes a number of compounds derived from alizarin, and is an extension of several previous specifications. Some new reactions of the polyhydroxyanthraquinones are also described. A new alizarin derivative is formed by applying the process described in Eng. Pat. 8725 of 1890 (this Journal, 1891, 337) to the pentahy-

droxyanthraquinone obtained from symmetrical dihydroxybenzoic acid and gallic acid. A sulphuric ether of the dyestuff is obtained as an intermediate product capable of dyeing mordanted wool, and can be converted into the dyestuff in the well-known manner. About 10 kilos. of pentahydroxyanthraquinone are mixed with 200 kilos. of fuming sulphuric acid, containing 80 per cent. of SO_3 , and allowed to stand at 30°C . for 24 hours. The solution is poured on to ice, heated to boiling, and the precipitate filtered off. In order to convert it into the dyestuff it is dissolved in soda-lye, boiled, and hydrochloric or sulphuric acid added in excess, when the new dyestuff separates as a fine precipitate which is filtered off and washed. It dyes wool reddish-violet when mordanted with alumina, and violet when mordanted with chromium salts. According to Eng. Pat. 13,677 of 1891 (this Journal, 1892, 740) the hexahydroxyanthraquinone there described is produced from anthrachrysone by oxidation with sulphuric anhydride. It has now been discovered that the oxidation may be performed with manganese dioxide, the anthrachrysone being dissolved in ordinary (66°B .) sulphuric acid. The oxidation may be performed at high or low temperatures, but in the latter case more manganese dioxide is required, and an anthradiquinone, identical with the diquinone of hexahydroxyanthraquinone of Eng. Pat. 4871 of 1891 (this Journal, 1892, 513), is formed as an intermediate product. It is converted into the hexahydroxyanthraquinone by heating with water or reducing with sulphurous acid. By applying the reaction described in Eng. Pat. 12,715 of 1890 (this Journal 1891, 759) to the sulphuric ether of hexahydroxyanthraquinone, viz., by dissolving this body in concentrated liquid ammonia, a new dyestuff is obtained which dyes wool mordanted with chromium salts a pure blue. Certain of the polyhydroxyanthraquinones can be converted into dyestuffs soluble in water by the action of strong nitric acid. The following bodies have been treated in this way: the tetrahydroxyanthraquinone of Eng. Pat. 8725 of 1890 (this Journal, 1891, 537), the penta- and hexahydroxyanthraquinones of Eng. Pat. 4871 of 1891 and the hexahydroxyanthraquinone of Eng. Pat. 17,712 of 1890 (this Journal, 1891, 917), obtained from alizarin bordeaux according to Eng. Pat. 18,729 of 1890 (this Journal, 1891, 917) or from anthraquinone according to Eng. Pat. 13,677 of 1891, or from anthrachrysone by oxidising it with strong fuming sulphuric acid or by other processes. The following are the stages of the reaction. The compounds are first nitrated, and one hydrogen is replaced by hydroxyl, and finally the bodies are oxidised by the nitric acid into quinones, so that they belong to the class of the so-called anthradiquinones, and are known as "nitrohydroxyanthradiquinones." The process is carried out by adding concentrated nitric acid of sp. gr. 1.5 to the alizarin bordeaux suspended in an indifferent solvent such as glacial acetic acid, petroleum ether, or chloroform, or else by exposing the dry powder in shallow trays to the fumes of concentrated nitric acid. The colouring matters dissolve in water to a dark red-coloured liquid, which, on standing, boiling or reducing with sulphurous acid gives a precipitate of a nitrohydroxyanthraquinone which crystallises from acetone and alcohol in red needles with a metallic lustre. Hexahydroxyanthraquinone in this manner yields a dinitrohexahydroxyanthraquinone, whilst alizarin bordeaux and alizarin pentaeryanine yield the same mono-nitropentahydroxyanthraquinone. The dyestuff soluble in water obtained from the hexahydroxyanthraquinone of Eng. Pat. 17,712 of 1890, 18,729 of 1890, and 13,677 of 1891, crystallises readily. Ammonia dissolves it with a greenish-blue colour, whilst sodium carbonate and caustic soda dissolve it to a blue solution, and give a greenish precipitate on adding an excess of the reagents. It differs from the hexahydroxyanthraquinone in not showing an absorption spectrum when dissolved in sulphuric acid, the colour of the solution being blue. It dyes wool mordanted with chromium salts greenish-blue to bluish-black, whilst alumina produces a heliotrope colour. The other colouring matters of this class dye from bluish-red to greenish-black, and on account of their solubility in water can also be used for printing.

The Manufacture of New Colouring Matters. B. Willeox, London. From the "Farbenfabriken vormals F. Bayer and Co., Elberfeld," Germany. Eng. Pat. 22,641, December 28, 1891.

ACCORDING to Clève three α -naphthylamine- β -monosulphonic acids are obtained by nitrating naphthalene- β -monosulphonic acid or sulphonating α -nitro-naphthalene and reducing the mixture of nitro-derivatives thus produced. The following are the acids according to Clève's nomenclature:—

Of these the β - and δ -acids are of particular value in the formation of colouring matters, since, when combined with tetrazo-compounds they yield dyestuffs which can be diazotised on the fibre and combined with phenols or amines, &c., a property not possessed by other α -naphthylamine sulphonic acids. A variety of dyestuffs can be obtained from these compounds in a manner similar to the processes described in Eng. Pat. 16,484 of 1887 (this Journal 1888, 619). The following are some typical examples. 1. One molecular proportion of tetrazodilolyl is combined with two molecular proportions of Clève's β -acid, forming the dyestuff—

This is diazotised and combined with two molecular proportions of naphthionic acid in presence of acetic acid, and gives a colouring matter which dyes unmordanted cotton a deep bluish-black. 2. The tetrazo solution from o -diamidodiphenol dimethyl ether is combined as before with two molecular proportions of Clève's β -acid, forming—

This compound is then diazotised with two molecules of sodium nitrite and combined with one molecular proportion of 1.4 naphthylamine sulphonic acid in presence of sodium acetate. When the combination is complete an alkaline solution of one molecular proportion of 1.4 naphthol sulphonic acid is allowed to run in, the solution being kept alkaline by means of sodium carbonate. A bluish-black dyestuff for unmordanted cotton is thus obtained. In the above process other amines and phenols, &c., can be substituted for the naphthol and naphthylamine sulphonic acids in the second stage, and other tetrazo compounds can also be used. The colours obtained dye a greenish and blue-black. 3. Tetrazo-diphenyl chloride is combined with one molecular proportion of Clève's β -acid. The free amido group is diazotised and the tetrazo chloride so obtained is combined with two molecular proportions of 1.8 dihydroxynaphthalene- α -monosulphonic acid. 4. In the preceding example the intermediate tetrazo compound may be combined first with one molecular proportion of β -naphthol-mono-sulphonic acid F and afterwards with one molecular proportion of the 1.8 dihydroxynaphthalene- α -monosulphonic acid. Both these colouring matters dye unmordanted cotton bluish-black from an alkaline soap bath. 5. Valuable disazo colouring matters, which dye wool bluish-black from an acid bath, are obtained by combining a diazotised amine with Clève's β - or δ -acid, rediazotising the amido-azo compound formed, and combining this with a phenol or amine, &c. As an example, 9.3 kilos. of aniline are diazotised by means of hydrochloric acid and 7 kilos. of sodium nitrite and added to a solution of 24.5 kilos. of the sodium salt of Clève's β -acid and 50 kilos. of sodium acetate. The resulting amido-azo-compound is diazotised with 7 kilos. of sodium nitrite and hydrochloric acid, and combined with 26.2 kilos. of 1.8 dihydroxynaphthalene- α -monosulphonic

acid in an aqueous solution, together with about 50 kilos. of sodium acetate. When the combination is complete the solution is made alkaline and the dyestuff salted out, filtered, pressed, and dried. It has the following formula—

and dyes unmordanted wool bluish-black from an acid bath, whilst the shades on wool mordanted with chromium salts are greenish-black. When used for printing it gives a pure black.—T. A. L.

V.—TEXTILES: COTTON, WOOL, SILK, Etc.

The Specific Gravity of Textile Fibres. L. Vignon. Bull. Soc. Chim. 7—8, 1892, 247—250.

THE author has determined the densities of the more important textile fibres with a hydrostatic balance sensible to $\frac{1}{100}$ of a milligramme. As the fibres occlude gases and are to some extent water-repellent, benzene was employed instead of water as the immersing fluid. The gases were eliminated by placing the balance in a suitable apparatus and reducing the pressure of the enclosed atmosphere to 50 mm. for 5 to 10 minutes. The following results were obtained:—

SPECIFIC GRAVITIES AT 18° OF TEXTILE FIBRES CONTAINING THEIR NORMAL AMOUNT OF MOISTURE.

Fibre.	Condition.	Specific Gravity.

—E. B.

The Specific Gravity of Silk. L. Vignon. Bull. Soc. Chim. 7—8, 1892, 249—250.

THE density of silk in various states, namely, raw, un-gummed, dyed, and weighed, was determined in the manner described above (preceeding abstract). The results are as follows.

The presence of tannic acid very slightly increases the density of the fibre. Metallic compounds cause a considerable increase. (See also this Journal, 1892, 600 and 640.)

Condition of Silk.	Increase or Decrease in Weight caused by Treatment Indicated.	Sp. Gr.

PATENTS.

An Improved Water and Grease-proof Packing Material. J. A. Turner, Lancaster. Eng. Pat. 15,899, September 19, 1891.

PAPER and canvas or other suitable woven fabric are united together by means of size or other similar grease-proof, adhesive material; the surface of the woven fabric is then coated with tar or other waterproofing material.—A. G. B.

Improvements in and relating to the Manufacture or Production of Paper Pulp and Textile Fibre. C. G. Hagemann, Ludwigsbafen, Germany. Eng. Pat. 18,470, October 27, 1891.

See under XIX., page 1026.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

Cause of the Greening, during Milling, of Logwood-Black on Wool. O. Walther. Färb. Zeit. 1892, 305—308.

THE greening or lightening of logwood-black on wool, which takes place to a greater or less extent during the milling and finishing operations, has been attributed to the omission of tartar from the mordanting bath, and to inefficient oxidation of the logwood. But it cannot be due

to either of these circumstances, for logwood-blacks of satisfactory fastness are obtained without the use of tartar, and it is well known that a good black cannot be obtained with logwood which has been injuriously or insufficiently oxidised, so that the defect in shade exists, in the latter case, prior to milling. The author traces the cause to difference in the dyeing characters of the various kinds of wool, to imperfect removal of the wool-yolk in scouring, and to prolonged milling necessitated by the deterioration of the felting property of the wool by the chromic acid mordanting bath, such prolonged exposure of the colour lake to a heated alkaline solution being the chief factor in its destruction, which is aided by the friction of the rollers or other apparatus employed. The effect of the first of these causes is seen on mordanting and dyeing together a number of samples of various kinds of wool, the blacks produced being of various shades and exhibiting a slight difference in their ability to withstand milling. The effect of the presence of grease in the wool is to prevent the colour-lake depositing in an intimate state in or upon the fibre. To show this and also the injury to the felting property accruing from the employment of chromic acid in mordanting, samples of imperfectly-cleansed and of well-cleansed wool were severally mordanted with iron and chrome, dyed with logwood, and milled. The samples dyed iron-logwood black were sufficiently milled in 6½ hours, those dyed chrome-logwood black required 16 hours. The latter were found to have lost more colour than the former, and the imperfectly-scoured samples much more than the well-scoured. The difference in the two lots of wool dyed iron-logwood black was less apparent. This injurious action of chromic acid on wool has induced many dyers to replace it in part by copper sulphate, or to employ a smaller proportion than usual, and to supersaturate the mordanted material with colouring matter to obtain the desired intensity of shade; or, again, to sadden with ferrous sulphate the material thus supersaturated. The last of these methods yields a colour-lake which is to a large extent superficially deposited on the fibre, and hence readily detached on milling. The excess of colouring matter absorbed according to the second method is also readily removed. The first method alone gives a satisfactory result. Thus, an excellent black of a superior degree of fastness to both milling and light (see also this Journal, 1891, 460) is obtained by mordanting with 2 per cent. of potassium bichromate and 2 to 2½ per cent. of copper sulphate, of which one-third can be advantageously applied after dyeing.—E. B.

Peroxide of Sodium and its Application in Bleaching.
Prud'homme. Monit. Scient. July 1892, 495—496.

UNTIL a short time ago this substance was only known as a rare product of the laboratory. The peroxides of potassium and sodium were first described by Gay Lussac and Thénard in 1810. In 1876 Fairley obtained the sodium compound in a crystalline form of the following composition $\text{Na}_2\text{O}_2 \cdot \text{H}_2\text{O}$. H. Carrington Bolton prepared it in 1886 by dropping sodium into potassium nitrate.

The peroxide has lately been put on the continental market at a price of 5 francs per kilo. The German Patent deposited on 3rd February 1892, is not yet published and therefore the mode of preparation is at present unknown. The substance as sent out is of a yellowish-white colour, partially powdered, and dissolves in water with a notable rise in temperature and the disengagement of a certain amount of oxygen. It is very hygroscopic, gaining 20 per cent. in weight after 24 hours' exposure to the air. On heating it with aniline, azobenzene is formed. If water be added to the mixture, or to a mixture of peroxide and benzene, flames are produced, and in the latter case an explosion.

The peroxide contains about 20 per cent. of oxygen available for bleaching purposes, corresponding with the formula Na_2O_2 (20·15 per cent.). This percentage is very high, barium dioxide containing 8 per cent., and peroxide of hydrogen (12 vols.) only 1·5 per cent. It is decomposed by dilute acids, and a solution of peroxide of hydrogen may in this way be prepared.

Cellulose is strongly attacked and turned yellow by a 15 per cent. solution. If it be then washed and treated with dilute acid, it will take a darker shade when dyed with Methylene blue, in this way resembling "mereerised" cotton.

The sodium compound, on account of its strongly alkaline reaction, cannot be directly employed in the bleaching of fibres of animal origin, such as wool or silk. In this case de Haën recommends that peroxide of magnesium be employed. The author has previously studied its action in bleaching (this Journal, 1891, 834) and showed that it possessed greater stability than peroxide of hydrogen. In application, 3 parts of sulphate of magnesia, which must be free from chlorine, are added to 1 part of sodium peroxide proportions which allow a slight excess of the former salt, as shown in the following equation—

Method of Bleaching. (de Haën.) *Wool*.—Well scour the wool and enter into a bath containing 30 kilos. of sulphate of magnesia to every 100 kilos. of wool. Temperature of bath 30° C. Turn several times, lift, and add 10 kilos. of the peroxide, re-enter, and heat up to 60°—70° C., and keep at that for one hour; lift and pass through a weak sulphuric acid bath to get rid of magnesia, rinse, and dry as usual.

Tussah Silk.—Prepare silk in usual way, taking care to remove all soap by repeated washing. For every 100 kilos. of silk use 2,500 litres of water at 30°—35° C. Dissolve 90 kilos. of sulphate of magnesia in the bath, give silk 3—4 turns, and lift. Add in 2—3 lots, 30 kilos. of peroxide and note that the bath be well stirred after each addition. Heat up to 80°—95° C. and keep the silk in the bath for 1½—2 hours. Remove magnesia by passing through weak sulphuric acid, wash and dry, or pass on to dyer. This method is applicable to ivory, feathers, bone, or hog's bristles.

"Chappe" Silk.—Clean the silk in the ordinary manner and enter into a bath containing 2,500 litres of water to every 100 kilos. of silk to which have been added 36 kilos. of sulphate of magnesia; give several turns, lift, and add in small quantities 12 kilos. of the peroxide, stirring well. Work for ¾ hour at 95° C. and once or twice bring just up to a boil, and take out after 1 to 1½ hours. Acidulate with sulphuric acid as above, wash, and dry.

Half-Silk Goods.—(Wool and silk, or cotton and silk). Prepare the goods before bleaching and remove all soap by repeated washing. Enter into bath containing 30—36 kilos. of sulphate of magnesia, according to colour. Give several turns and add the peroxide, 10—12 kilos., and keep for ¾ hour at 95° C., finally arriving at a boil. Pass through sulphuric acid. For 100 metres of cloth, 60 centimetres wide, and weighing about 5 kilos, use 250 litres of water.

W. P. D.

On the Resistance of Oxycellulose to Colouration by Tetrazoic Dyes. M. G. Saget. Monit. Scient. September 1892, 640—641.

Wirtz in 1882 found that oxycellulose was dyed by basic colouring matters but not by acid colouring matters. In view of this, experiments were made to ascertain the effects of the tetrazoic dyes, which are of an acid nature.

The author has experimented with several dyes of this kind and find that they stain oxycellulose but slightly, if at all.—A. L. S.

A New Process for Photo-Dyeing. A. Villain.
L'Amateur Photographe, 1892.

See under XXI., page 1031.

PATENTS.

A New or Improved Machine for Dyeing one or more Warps. E. Brook, Slaithwaite. Eng. Pat. 22,060, December 17, 1891.

THE machine consists of a central shaft, carrying two discs or wheels, capable of being rotated partly in and partly out of the dye-vat. Between the two discs are cross bars or plates arranged in radial series, and these carry the warp which is wound round them in a continuous manner. These bars or plates are provided with curved or rounded edges and are capable of oscillation (whereby the plates of one radial series come into contact with those of its neighbouring series) for the purpose of gripping or holding the warp as it emerges from the dye-liquor.—W. E. K.

Improvements in Colour-Printing and in Apparatus to be Employed therein. J. L. Davies, London. Eng. Pat. 22,093, December 17, 1891.

THE object of this invention is to apply printing ink in a circular, elliptical, or curvilinear direction to blocks or surfaces for the production of rainbow or iridescent effects, in a circular or elliptical form. For this purpose a taper or conical inking roller suitably mounted on a circular inking slab is employed.—W. E. K.

Improvements relating to Rollers for Printing Fabrics and Wall Papers. H. H. Lake, London. From La Société Evesque and Cie., Lyons. Eng. Pat. 16,958, September 22, 1892.

THE design is drawn upon a lithographic stone or in fat-inks upon transfer paper, and then transferred to a plate of zinc or other metal, which is subsequently immersed in an acid vat, whereby the parts not covered with fat-ink are etched to the depth required. From this plate an impression is pulled off on either paper or lead, and this impression is then wound on a roller of wood and placed in a two-part cylindrical mould, which is heated by gas or steam. The roller of wood is next withdrawn, the axis of the roller put back in its place, and then into the mould thus prepared a mixture is poured of fused unattackable metal or plastic material, such as india-rubber. After hardening, the roller is removed from the mould, and is ready for use. The design may be prepared either in relief or intaglio, as desired. By a modification, the rollers, when made of zinc, copper, or other metal attackable by acid are engraved direct by gently rolling them with pressure against the fat-ink transfer of the design, and then submitting them to the etching process by means of acid.—W. E. K.

Improvements in Dyeing Silk or Half-Silk Goods. E. Zillesen, sen., Crefeld, Germany. Eng. Pat. 22,538, 24 December 1891.

UNKNOWN silk, to be used for the warp of a fabric (the weft of which may be silk, wool, or cotton, dyed or undyed) is prepared before weaving with fat and a metallic mordant. The prepared and unprepared fibres are then woven together in any optional pattern, and on dyeing up the fabric the warp and weft give shades or colours different the one from the other.—W. E. K.

Improvements in the Production of Azo-Colours on Fibre. B. Willcox, London. From the "Farbenfabriken vorm. F. Bayer and Co.," Elberfeld. Eng. Pat. 22,641A, December 28, 1891.

UNMORDANTED cotton is dyed with the tetrazo-dyestuff formed by the combination of one molecular proportion of a tetrazo-compound of benzidine, its homologue or analogue, with (a) two molecular proportions of Clève's alpha-naphthylamine-mono-sulpho acid (either beta- or delta), or (b) one molecular proportion of each of these acids, or

(c) one molecular proportion of either of these acids and one molecular proportion of an amine, phenol, &c. of the benzene or naphthalene series. The dyestuff thus fixed on the fibre is next diazotised by immersion in an acidified solution of sodium nitrite; and the resulting diazo- or tetrazo-product is then coupled with an amine, phenol, amidophenol, &c. of the benzene or naphthalene series, by immersion in its acid or alkaline solution.—W. E. K.

VII.—ACIDS, ALKALIS, AND SALTS.

PATENTS.

Process and Apparatus for the Manufacture of Cyanides. G. T. Beilby, Slatford. Eng. Pat. 4820, March 18, 1891.

IN this process ammonia gas is caused to pass over or to bubble up through a fused mixture of anhydrous carbonate of an alkali and finely-divided carbon, to which a sufficient proportion of alkaline cyanide has been added to make the mixture fuse at a low temperature. When carbonate of potassium is used, the reaction goes on satisfactorily at a temperature somewhat below the melting point of pure carbonate of sodium. The cyanide may be tapped from the bottom of the vessel in which the operation is conducted, and the mixed materials are fed in at the top. In this way cyanide containing 70 per cent. of potassium cyanide can be obtained. Or the temperature and duration of the operation may be adjusted so that the cyanide is sublimed. Various forms of apparatus are described and drawings of them are given. A melting pot of cast iron may be used, with an inlet tube at the bottom for the ammonia and a delivery tube at the top by which the gases escaping are carried away. These are subsequently treated to recover sublimed cyanide and unaltered ammonia. Another form of apparatus is fitted with revolving arms, which move the melted mixture over a series of superimposed shelves, so that it drops downwards from shelf to shelf, meeting a stream of ammonia gas as it falls. The carbon may be supplied by charcoal, lamp-black, gas-black, coke, or pitch, &c. By using pitch or coke made from the basic tars or from the crude oils of shale, coal, or peat, a large part of the nitrogen they contain may be recovered as cyanide. The specification also provides for the use of "volatile alkaloidal bases" as a source of the nitrogen.—H. S. P.

Improvements in Generators to be used in the Production of Hydrogen Gas. W. Hawkins, T. Hawkins, H. Fuller, and W. H. Fuller, Portsmouth. Eng. Pat. 13,379, July 21, 1891.

THE apparatus consists of a copper or lead box divided into four partitions, the upper two containing the solution of an acid, and the two lower ones the zinc or other metal to be acted upon.—H. A.

New Solid Compounds of Sulphur Trioxide, Water, and the Bi-Sulphates or Acid Sulphates of Sodium or Potassium. G. F. Brindley, Handsworth. Eng. Pat. 17,796, October 17, 1891.

THE object of this invention is to obviate the difficulties of transporting sulphuric acid, and for this purpose it is proposed to heat sulphuric acid of various strengths with potassium or sodium bisulphate; the mass is then carefully evaporated at temperatures between 200°–300° C. The hot liquids are run into drums and allowed to set. The resulting compounds have the composition $\text{H}_2\text{SO}_4 \cdot \text{NaHSO}_4$ or $3 \text{H}_2\text{SO}_4 \cdot 2 \text{NaHSO}_4$ with 1 molecule of water.—H. A.

Improvements in Means or Process for Producing Carbonic Acid Gas. D. Rylands, Stairfoot. Eng. Pat. 18,231, October 23, 1891.

CARBONIC acid may be economically produced by first carbonising coal in retorts, collecting the illuminating gas given off, and then lowering the temperature to about 1,100° F. Air is now admitted in quantities "which can be regulated to the greatest nicety for securing the best results." The carbonic acid so evolved is taken by means of a separate main to a scrubber, and after cooling is passed through a tower provided with shelves, where it meets with a shower of sodium carbonate solution. The resulting sodium bicarbonate is fed into a boiler, the carbonic acid boiled off and collected in a holder, whilst the solution is pumped back on the tower for absorbing fresh quantities of carbonic acid.

An alternate method consists in burning in the retorts a mixture of coke and limestone.—H. A.

Improvements in the Manufacture of Salt. J. E. Bott, Stockport. Eng. Pat. 18,481, October 27, 1891.

The invention refers to the evaporation of brine. The apparatus consists of a cylindrical evaporating vessel suspended on hollow trunnions. One of these acts as part of the main flue from a furnace, in which air is heated under pressure; it is then continued to a chamber formed in the evaporating vessel by means of a diaphragm acting like a false bottom. The air thus heated, now passes through vertical perforated pipes which are covered with the solution. The other hollow trunnion serves for carrying away the steam and air, and for this purpose is separated from the rest of the vessel by means of a pocket reaching almost to the top lid. The waste heat may be utilised for heating up fresh quantities of solution in similar vessels arranged in series. After sufficient evaporation the vessel is disconnected, the lid unscrewed and the vessel discharged by tilting it over on its trunnions.—H. A.

Improvements in the Manufacture of the Oxides of the Alkaline Metals. H. Y. Castner, London. Eng. Pat. 20,003, November 18, 1891.

THE metallic sodium or potassium is placed in aluminium dishes or trays, which are placed on tram carriages running through an iron tube. The tube is built into a furnace and its ends are tightly closed by end-plates. Air is admitted at one end of the tube, passed through the tube and out at the other end. The tube is heated to about 300° C. The air is first freed from moisture and carbonic acid, and by its means a gradual oxidation of the alkaline metal takes place, the metal at the end nearest the entrance of the air being first converted into peroxide, whilst the air in travelling through the tube gradually becomes deprived of oxygen, so that the metal at the air-exit end undergoes oxidation very slowly in an atmosphere containing very little oxygen. As the finished product is drawn out at one end of the tube a fresh charge is inserted at the opposite end, the tram carriages being pushed along the tube to admit of fresh trays being placed in it.

Improvements in and Apparatus for the Manufacture of Alkaline or Earthy-Alkaline Bases, and of their Salts or Compounds by the Electrolysis of Saline Solutions. E. Hermite and A. Duboscq, Paris. Eng. Pat. 21,957, December 15, 1891.

See under XI., page 1015.

An Improved Process for the Preparation of Pure Nitric Acid. E. Edwards, London. From O. Guttmann and L. Rohrmann, Muskau, Germany. Eng. Pat. 22,481, December 23, 1891.

NITRIC acid prepared in the usual way by distillation, contains a varying proportion of lower oxides of nitrogen, such as nitrous acid, depending upon the amount of chlorine in the nitrate of soda used. These lower oxides have always been removed from the finished acid by heating it and blowing air through. This improved process effects the removal of the nitrous acid by blowing air into the gaseous acid before it is condensed. In this way the nitrous acid in the presence of the water in the acid, and air, is converted into nitric acid, the abstraction of the water resulting in a stronger distillate being formed, whilst the creation of a slight vacuum and the more rapid carrying forward of the acid vapours causes a more rapid distillation.

—H. S. P.

Improvements in the Production of Salts of Ferri-cyanogen. A. M. Clark, London. From the Deutsche Gold und Silber-Scheideanstalt, Frankfurt-on-Maine. Eng. Pat. 22,558, December 24, 1891.

IN the manufacture of alkaline ferri-cyanides, such as red prussiate of potash, by the oxidation of the corresponding ferro-salt by means of chlorine or bromine, the ferri-salt is obtained contaminated by the bromides or chlorides which pass into solution with it; or when an electric current is used for effecting the oxidation, caustic alkali is formed, and renders the ferri-cyanide impure. This invention obviates this difficulty by conducting the oxidation in presence of an alkaline-earth salt, preferably calcium ferrocyanide.

The following is stated to be the reaction when potassium permanganate is used for oxidising:—

The manganous oxide and the greater portion of the caustic lime remain undissolved. After filtering, the small quantity of caustic lime in solution may be precipitated by carbonic acid. The electric current may also be used for oxidising, and an equally pure product obtained. If chlorine or bromine be used, a better yield is obtained by introducing the calcium ferrocyanide, although the resulting product is not so pure. A double ferrocyanide of an alkali and alkaline earth may be used instead of mixing the two salts.—H. S. P.

Improvements in the Manufacture of Carbonates of Strontium and Barium. J. Brock and J. T. Marsb, Widnes. Eng. Pat. 22,541, December 24, 1891.

IN the usual method of manufacturing these carbonates, the bases are obtained in solution as sulphides or hydro-sulphides. On treating this solution with carbonic acid gas the base is precipitated as carbonate. But owing to the presence of polysulphides in the solution and of traces of oxygen in the carbonic acid gas, some free sulphur is always precipitated with the carbonate of strontium or barium, and, combining with the carbonate during the subsequent operation of drying, spoils the product.

The patentees remove this sulphur by boiling the precipitated carbonate suspended in water with the corresponding hydrate of the base. About 2 cwt. of strontium hydrate crystals suffice to remove the sulphur from an amount of the precipitated carbonate of strontium equal to one ton of the dry carbonate, and in the case of barium about 2½ cwt. of crystallised barium hydrate is required. The sulphur combines with the hydrate, and the operation is usually effected after boiling for about half an hour. The precipitated carbonate is then separated by a filter-press or in any other way, washed and dried. The solution of hydrate from the press may be used for dissolving a fresh portion of sulphide, and after crystallising out the hydrate, treating the mother-liquor with carbonic acid gas, by which means the strontium or barium in solution is recovered without loss.—H. S. P.

Improvements in Apparatus for Evaporating and Incinerating Spent or Used Alkaline Lyes or similar Waste Products. A. S. Caldwell, Lasswade, N.B. Eng. Pat. 192, January 5, 1892.

THE improved apparatus comprises a "splash" chamber and incinerating furnace. The "splash" chamber has a pan-shaped bottom upon which the more or less concentrated lye is run from a tank. Over one end of the chamber is a circular tower, whilst at the other end are three hearths arranged in steps one below the other, the height of each step being such as to enable a door to be placed at the end of each hearth through which a tool may be thrust for raking the drying material from one hearth down on to the next one below it, and for raking the incinerated material out of the lowest one. On either side of the end of the lowest hearth is a small fire-grate for burning the fuel which dries and incinerates the lye. The hot gases from these grates pass over the hearths and through the splash chamber, up the tower, and then down into a flue, where they are drawn away to a chimney, an increased current being also obtained by means of a fan or blower placed at the bottom of the flue from the tower. In the splash chamber are a number of paddles which throw up the liquor in spray, thus assisting the evaporation of the liquid. When sufficiently dried in this chamber the material is then raked on to the first hearth, and afterwards on to the second, and finally on to the third, where its incineration is completed. To prevent particles of lye being carried away in the opposite direction by the current of gases, screens are hung in the splash chamber, and the object of the tower over the end of the splash chamber is to further allow of the deposition of liquid and prevent it being carried into the flue. By a modified form of tower the deposition of liquid is further assisted by the gases being caused to pass upwards in a helical manner, so that the globules of liquid are thrown against the side of the tower. There are other details of construction, including air passages in the walls of the furnace, where air is heated by radiated heat from the furnace.—H. S. P.

Improvements in Means or Apparatus for the Manufacture of a Mixture of Hydrochloric Acid Gas and Air. La Société A. R. Peehiney et Cie., Salindres, France. Eng. Pat. 8276, May 2, 1892.

THIS improvement refers to apparatus for the production of a mixture of gaseous hydrochloric acid and air from solutions of hydrochloric and sulphuric acids.

The apparatus consists of a vessel where the acid solutions mix and from whence they overflow into a tower packed with flint. A current of air passes up this tower, liberating the hydrochloric acid and eventually mixing with the whole of the gas given off. The resulting gas mixture may be used for the preparation of chlorine by the Deacon process.

The mixing of the acids proceeds in a closed vessel divided by means of a partition wall into two unequal parts, which communicate on the tops and on the bottom. The narrower part is provided with shelves to produce a better mixture of the liquids, which then pass under the partition-wall and rise to a certain height in the second compartment, finally overflowing into the tower. On the other hand, the hydrochloric acid gas given off in the first compartment passes above the partition-wall into the second compartment, and from thence into the tower, forming one stream with the hydrochloric acid gas given off there.—H. A.

Improvements in the Method of and in Apparatus for the Production of Carbonic Acid Gas. W. Stones, R. Bardsley, and T. H. Hayes, Manchester. Eng. Pat. 15,275, August 25, 1892.

THE apparatus is to regulate the supply of gas from a carbonic acid gas generator (in which the gas is generated by acid from a carbonate) according to the required rate of consumption. The gas passes from the generator into the lower part of a closed vessel containing water, whence it is drawn away as required by a pipe at the top of the vessel. There is also a pipe in the lower part of this vessel, which connects it with an open vessel placed on a higher level.

The pressure of the gas on the surface of the water in the closed vessel forces some of the water up into the open vessel, and the level of the water in the latter vessel rises and falls according as the pressure of the gas above the surface of the water in the closed vessel increases or diminishes. By means of a floating ball on the surface of the water in the open vessel, to which a lever is attached, a valve is opened or closed in a third vessel containing acid, so that when the consumption of gas is increased and the pressure in the closed vessel falls, causing a corresponding fall of level of water in the open vessel, the valve in the acid tank is opened, allowing more acid to flow into the generator and thus increasing the supply of gas; and on the contrary, when the consumption of gas is decreased, the ball floats rises and effects the closing of the acid valve, thus diminishing or cutting off the supply of acid to the generator.—H. S. P.

New Process for the Production of the Cyanides of the Alkalis and Alkaline Earth by the Simultaneous Employment of a Hydrocarbon and Ammonia Gases, with the addition, if desired, of Free Nitrogen. H. J. Haddan, Loudon. From the Viscount of Lambilly, Paris. Eng. Pat. 15,513, August 29, 1892.

THE process consists "in the simultaneous decomposition by heat of a mixture of hydrocarbon gas with ammonia gas, to which it is of advantage to add also free nitrogen, in the presence of an easily cyanisable alkali or alkaline earth, such as the carbonates or oxides of potassium, sodium, or of barium."

The free nitrogen is obtained by passing air over copper at a red heat. The hydrocarbon gas may be obtained in any of the known ways, by distillation of coal or animal or vegetable matter, and the distillation should be carried on at as low a heat so as to obtain a gas as richly carburetted as possible. Two methods are described for increasing the proportion of hydrocarbons in the gas, the one by passing the gas over the copper oxide obtained in making oxygen-free nitrogen at a red heat, thus removing a portion of the free hydrogen and a part of the combined hydrogen; and the other, which forms one of the claims in this patent, by passing the gas through a series of cylinders filled with pieces of carbon impregnated with a liquid hydrocarbon, such as coal-tar or heavy oils, or a mixture of carbon and powdered rosin, the cylinders being heated to a temperature below that at which the hydrocarbons commence to distil varying from 40°–50° for petroleum oils up to 300°–350° for rosin. Gas already used for cyanisation may be re-carburetted in this way and so used over and over again. The ammonium gas may be obtained in any known way. It is collected in a gasometer to be mixed either with the hydrocarbon gases alone or with these and with free nitrogen.

The material to be converted into cyanide is prepared by adding "to a concentrated solution of carbonate or oxide of potassium or sodium at least 100 parts of powdered carbon for every 100 parts of alkali. This solution is evaporated to dryness and 20–30 parts of powdered chalk and 50 parts of iron filings added. It is useful to agglomerate this mixture by adding pitch or tar" and making it up into briquettes. This mixture is charged into iron cylinders and heated until gases cease to be evolved, the evolution being assisted by exhausting the cylinders with a pump. When no more gas comes off, the mixture of hydrocarbon, ammonia, and nitrogen gases is passed into the cylinders under slight pressure. After cyanisation the mass in the cylinders is withdrawn and lixiviated as in the ordinary processes to obtain the ferrocyanide of the alkali used. The solid residue is used again in the process, serving as an absorbent for a fresh solution of alkali. (See also this Journal, 1891, 642, and 1892, 604).—H. S. P.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

PATENTS.

Improvements applicable to Furnaces or Retorts used in the Production of Glass and for similar Purposes. D. Rylands, Stairfoot, Yorks. Eng. Pat. 18,230, October 23, 1891.

THE invention relates to utilisation of waste heat in the process of glass manufacture by the action of superheated steam upon sand mixed with chlorides. In the first place a suitable floor is fixed over the crown of the melting furnace, the heat from which evaporates to dryness the solution of chloride of calcium which is brought from the bleach-powder works. The calcium chloride is then mixed with salt and sand in a chamber which is kept at a proper temperature for the dry-mixing of a hygroscopic body by the waste heat from a flue and retort below. It is in this retort where the chemical action takes place, superheated steam being admitted and glass "frit" and hydrochloric acid formed. The frit is passed into the melting furnace and the hydrochloric acid gas is carried over by a pipe and condensed in the usual way.—V. C.

An Improved Process for the Electro-deposition of Metal upon the Surface of Glass, Porcelain, China, Earthenware, and other Materials. A. S. Ford, London. From H. Pottier, Paris. Eng. Pat. 18,256, October 23, 1891.

THE difficulty of obtaining a satisfactory metallic coating by means of electro-deposition upon glass, porcelain, and earthenware, is in this invention overcome by applying to the surface of the article a paste containing borate of lead, finely-divided silver, and oil. The article is then heated in a muffle furnace, after which the surface will receive a firmly adherent deposit by electro-deposition.—V. C.

Improvements in the Construction of Tank Furnaces for the Manufacture of Glass. T. C. J. Thomas, London. Eng. Pat. 19,777, November 14, 1891.

IN a former patent granted to the inventor (Eng. Pat. 12,076 of 1886) a process is described for eliminating impurities in the frit by the action of a blast of oxygen or air.

The present invention relates to the construction of a tank furnace for carrying out this process, the wall of the furnace being provided with one or more downward inclined gas passages, having their outlet ends terminating below the level of the frit. The passages, which are lined with refractory material, are connected with a common supply pipe provided with a regulating valve.—V. C.

A New Product to serve as a Substitute for Pottery for Filtering Purposes, and for the Manufacture of Tobacco Pipes and the like. J. E. G. Méran, Paris. Eng. Pat. 20,861, November 30, 1891.

ASBESTOS fibres are of smaller diameter than any others, whether of animal, vegetable, or mineral origin, and yield on pulverisation particles so fine that when agglomerated and moulded into a suitable form a filtering medium is obtained which will not allow bacteria to pass, and is therefore eminently suitable for sterilising liquids. After a filtration the material may be cleansed by heating. The material is also suitable for the bowls of tobacco pipes and may be used as a substitute for ceramic ware generally.

—V. C.

An Improved Process for Producing Colours on Glass Surfaces. J. C. Duntze, Frankfort. Eng. Pat. 16,241, September 10, 1892.

PREVIOUS to this invention coloured designs produced upon glass by mechanical means have never possessed sufficient transparency to form a perfect substitute for stained glass. In this invention the required transparency is obtained by means of the following process:—The transfer colours are taken off on transparent transfer paper, which before being moistened, is pressed against the surface of the glass by rubbing until the colours begin to adhere. It is then moistened and further rubbed until the moisture has nearly, but not quite, disappeared from the paper, whereupon the paper is taken off.—V. C.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Portland Cement and Portland Cement Concrete. H. K. Bamber, E. A. Carey, and W. Smith. Proc. Inst. Civil Eng. 107, Session 1891—92.

ONE of the meetings of the last session of the Institution of Civil Engineers was devoted to the reading of three papers upon the subject above mentioned, and two subsequent meetings to the discussion which was taken on all three papers at once, as they were of cognate import. The first paper was by H. K. Bamber, on "Portland Cement, its Manufacture, Use, and Testing." With regard to the testing it is pointed out by the author in this paper, that the usual method of ascertaining whether the cement has been burnt hard enough, namely, the weight per bushel, is fallacious, as many causes other than the true density of the cement particles, affect the results. He urges the substitution of the determination of the specific gravity, stating that a good cement, when new, will have a sp. gr. of 3.1 to 3.15, while if it fall below 2.9 the cement has either been improperly burnt, or has become deteriorated by exposure to the air. He details his method of taking the specific gravity of cement, water being used instead of turpentine, which is generally adopted because of the action of water on cement even when the exposure is short. The alteration is made on the ground that the expansion of turpentine by rise of temperature is inconveniently great. He deprecates the practice of aerating cement with a view of rendering it free from tendency to blow, stating that with a well-burnt cement of proper composition such a process is unnecessary. The fineness should be such that the whole of the cement would pass through a sieve having 2,500 meshes per square inch, and not less than 90 per cent., through one with 5,625 meshes. Experiments were made on the proper proportion of water with which to mix concrete. Blocks composed of four parts of shingle, two of sand, and one of cement, were used, the cement being newly ground. It had the following composition:—

Silica.....	23.32
Alumina and ferric oxide.....	12.13
Lime.....	61.56
Magnesia.....	1.07
Sulphuric acid (sic).....	1.28
Carbonic acid.....	0.30
Organic matter and loss.....	0.34
	<hr/> 100.00

Three sets of blocks of the mixture given above were made in duplicate with varying proportions of water. The first were mixed with as much water as the cement would take up, which proved to be 10 lb. for each block. The second with 7.5 lb. of water, the third pair with 5 lb. After standing for a fortnight one of each of these sets was placed on a sea wall for 12 months, being constantly covered and uncovered by the tide. On breaking them at the end of

the test it was found that the one with 10 lb. of water was hard and sound and dry throughout; that with 7.5 lb. was dry in the middle, but on every side the water had penetrated about 3 in. and had much weakened the block; that with 5 lb. was wet right through, the sea water having been able to percolate through the block and remove much of the lime. It was quite weak. The check experiments were made on the remaining blocks of each set, fresh water being, however, used instead of sea water, the penetration of the water being similar to that observed with the previous specimens. It was noticed that with No. 1 (that with 10 lb. of water) the water in which it stood remained clear; with No. 2 the water became turbid from the presence of carbonate of lime; and in the case of No. 3 the turbidity was greater, and at the end of 12 months the whole block being covered with crystals of carbonate of lime, $\frac{1}{4}$ to $\frac{1}{2}$ in. in thickness. The experiment on the blocks exposed to the sea gave the same results when extended to three years. The influence of the quantity of water in concrete on its porosity was shown by the following experiments. Blocks were made consisting of 5,184 cub. in. of shingle, 2,592 cub. in. of sharp sand, 1,296 cub. in. of cement mixed with 30 lb. of water, and this amount sufficed to exactly fill a box 18 in. cube. Another mass, precisely the same in composition save that 15 lb. of water were used instead of 30 lb., more than sufficed to fill the same box, only seven-eighths of the mixture being contained by it. The obvious deduction is that the latter was more porous than the former. The author concludes that it is necessary, in order to secure sound concrete, to ensure its being thoroughly wet so that it may be non-porous, and the water with which it may be placed in contact be prevented from washing in and out. In the case of sea water this is especially important, because of the well-known destructive action of the magnesium salts therein on the lime compounds in the cement, should it obtain access to the heart of the work. Attempts to make the concrete extra strong by mixing it as dry as possible defeat themselves.

A paper was read on "The Inspection of Portland Cement for Public Works," by A. E. Carey. Dealing with the raw materials the author states that the average proportion of coarse sand as determined by elutriation, is 3 per cent. in gault clay, and in Gillingham mud 7.9 per cent. Grey chalk is more easily washed than white, but needs greater vigilance with the calcimeter owing to its more variable composition. The fine state of division of the carbonate of lime left as a waste product in Chance's sulphur recovery process, recommends it as a raw material for the manufacture of cement. The wash mill should be driven at about 22 revolutions per minute, and the minimum of water should be used; 25 per cent. suffices. Assuming the ordinary semi-dry process to be used, the wet grinding after the cement comes from the wash mill must be sufficient to reduce the raw materials to a point at which the dried slurry leaves not more than 8 per cent. on a sieve having 22,500 meshes per square inch. So good a result is difficult to attain, and it is usual to pass a handful of the slurry through a 1,600 or 2,500 mesh sieve, testing the fineness by the absence of grittiness to the touch. As has been shown by Le Chatelier the spontaneous disintegration of clinker is due to the presence of dicalcium silicate (this Journal, 1888, 567).

The picking out of the pink and yellow underburnt clinker is most important, and in one specification mentioned it is insisted that this shall be done by daylight. As long ago as 1865 Sir F. Bramwell pointed out that the specific gravity of cement is one of the data by which its quality can be judged. The weight per bushel should be abandoned as too inexact to be useful, and the determination of the specific gravity adopted to its stead. With regard to the fineness of cement the old demand for a residue not exceeding 10 per cent. on a sieve with 2,500 meshes per square inch is fast becoming obsolete, as it is really only the floury part of cement that has any cohesive properties. The residue left on a sieve with 32,257 meshes per square inch (5,000 per square cm.) has practically no cementitious value. The increased value of a finely-ground cement is more apparent with sand than with neat tests. The practice of sifting the cement as it comes from the stones does not necessarily conduce to finer grinding, as the miller, trusting to his sieves

to reject the coarser particles, might set his stones so as to produce a cement of coarser average than would be possible if grinding without sieves. The following figures show the effect of fine grinding. The cement used had a specific gravity of 3.125, and was gauged with three parts of standard sand to one of cement, and 10 per cent. of water, at a temperature of 46° F. The mean results for six briquettes for each test at 28 days were:—

	Tensile Strength Lb. per sq. in.
Original cement, 9 per cent. on a sieve with 2,500 meshes.....	220
Cement with residue above mentioned removed.....	304
With residue on a 5,025 sieve removed.....	311
With residue on a 32,257 sieve removed.....	360

Cement, as it leaves the stones, has a temperature of 150°—160° F., and in grinding to a fineness corresponding to a residue of 8 per cent. on a 2,500 mesh sieve, a pair of 4½ ft. stones running at 140 revolutions per minute produces 25—32 cwt. per hour, and absorbs 35 to 40 horse-power. Edge-runners do not appear to yield good results, from the absence of the shearing action characteristic of stones. Modern modifications of the edge-runner, however, may give cement that is of higher strength for the same degree of fineness than that from stones, while in one case mentioned the power absorbed per ton per hour was 14.96 horse-power, and the cement left the mill at a temperature of 77°—75° F. In the author's opinion aeration is desirable to remove the baneful effects of free lime, and he suggests that in view of the change that cement often suffers on long voyages, it might in some cases prove convenient to export clinker and grind it at its destination. With respect to testing he is in favour of the 1 in. × 1 in. briquette; even a half-inch size might be useful for rapid testing. He recommends the Dietrich form of calcimeter, and doubts the advisability of introducing compressive tests into ordinary specifications. He deprecates the issue of standard regulations for the testing of cement such as are in use in Germany, France, Russia, and elsewhere, as it might tend to check the progressive improvement in quality that has been so marked a feature of late years when no such standard existed in this country. There is, however, appended to his paper a specification that might serve as a standard, should one be adopted. Its chief point of novelty is the insistence on the necessity of determining the specific gravity, which is fixed at a minimum of 3.1. The Arnold apparatus for making briquettes without hand-trowelling, although ingenious, should not displace ordinary gauging by hand, as the operator is better able to judge the quality of the cement by actual manipulation. An objection to the apparatus is that it is more favourable to a light than a heavy cement, as owing to its greater volume the former is more compressed than the latter. A quick setting cement is put at a disadvantage, as the immersed face becomes set before the water penetrates to all parts of the briquette. Further, as the briquettes are dealt with in a series at one operation, the weight of the water absorbed by each cannot be accurately measured. Its results cannot usefully be compared with those got by hand gauging. Although in gauging briquettes for tensile tests the smallest proportion of water that can be used gives the highest results, yet higher figures are obtained in compressive tests when plenty of water is taken. Thus a cube made of one part of cement and three of normal sand gauged with 10 per cent. of water had a crushing strain of 1,425 lb. per square inch, while one with 20 per cent. of water crushed at a load of 1,679 lb.

Silt in the water used for making concrete has a deleterious influence on the cement. An experiment was made to show how far this occurred. Six briquettes were gauged neat with 20 per cent. of distilled water (the cement having a specific gravity of 3.1), and took three hours to set, and had an average tensile strength of 480 lb. per sq. in. Another test was made, in which the water was mixed with one-fiftieth of its weight of Thames mud, corresponding to about one-hundredth by volume, and took four hours to set, and broke at 411 lb. Experiments were also made to ascertain the effect of frost on the strength of

cement, and are recorded in one of the appendices of the paper. Briquettes gauged with water at 55°—60° F. and immersed in water of the same temperature, had a tensile strength of 540 lb. at seven days, and one of 585 lb. at 14 and 28 days. Briquettes of the same cement, gauged in the same manner, but subsequently exposed to a temperature ranging from 22°—41° F. had a tensile strength of 357 lb. at seven days, 552 at 14 days, and 595 at 28 days. The deduction is therefore that exposure to frost only delays the increase of strength of cement, but does not affect the final result. (This Journal, 1889, 393.) The influence of frost on concrete may however be serious on account of the disruptive force of the frozen water it contains, and the best means for preventing it has occupied the attention of the Russian and American authorities. It has been found that the addition of common salt to the water, up to the proportion of 8 per cent., enables work to be carried on even in severe weather. The contrary effect to the retardation due to frost, is observed in work exposed to a tropical or sub-tropical climate. The author calls attention to the well-known phenomenon that the tensile strength of cement may fall off while the compressive strength continues to increase, and attributes it to a change in the molecular structure of the cement.

With regard to the effect of magnesia in cement, the author remarks that in the case of notorious failures that have occurred in cements from the presence of magnesia, the percentage of that substance is far in excess of the quantity existing in normal and marketable Portland cements. (This Journal, 1889, 781; also 1890, 943 and 1037.) He quotes the case of a failure of cement not containing excess of magnesia, but over-limed and under-burnt, in which a 6-in. flooring of concrete forced the walls of a building which were 18 in. thick, out of line, and eventually crumpled up the floor itself, causing it to assume a serrated form and finally to disintegrate, as an analogous instance of the blowing tendency of excess of basic material in the cement, whether in the form of lime or magnesia. He draws a clear distinction between the magnesia originally present in cement, due to the use of dolomitic raw materials, and that found in disintegrated concrete which has been exposed to the action of the sea, and has been derived from the sea water by the precipitating action of the lime in the cement, maintaining that the white deposits arising from the latter cause, are themselves harmless, and are only evidence that damage has already been done by the reaction with the lime of the cement aforesaid. Experiment made to test the porosity of concrete and the diminution in porosity by the application of a coat of cement or cement mortar, showed that concrete mixed in such proportions as one part cement, three parts beach, and three parts coarse sand, was fairly porous, an average leakage of one gallon a day through a plug 12 in. thick taking place under a head of 30 ft. of water. Stirring cement into the water resting on the plug, and allowing it to settle, had little effect in diminishing the leakage, as the cement did not set, and acted much as a similar amount of clay might have done. When the surface of the concrete was rendered with a layer of neat cement or of cement mortar laid evenly on, however, the leakage practically ceased. Cement grout run on to the surface of the concrete had little effect. In conclusion some results are given of the influence of sugar, carbonate of soda, and common salt on the strength of cement. The cement used had a specific gravity of 3.03, and left a residue of 9.5 per cent. on a 2,500-mesh sieve. It had a crushing strain at three months of 7,392 lb. per sq. in. when tested neat, and one of 2,112 when mixed with three times its weight of sand. The addition of 5 per cent. of common brown sugar caused three of the test-pieces prepared with it to fall to pieces before they could be placed in position in the testing machine; three others gave an average breakage strain of 2,557 lb. per sq. in. A similar experience is recorded with the sand tests, three of the test-pieces crumbling spontaneously and the remaining three giving a result of 1,358 lb. Twelve test-pieces containing 2.5 per cent. of sugar, with and without sand, all went to pieces; the contraction was more marked than with those containing 5 per cent. of sugar. In all cases a large quantity of

a tasteless gelatinous substance exuded from the blocks: they also contracted greatly on setting, especially the neat samples. With 2.5 per cent. of washing soda, a compressive strength of 2,862 lb. was observed with the neat cement, and 855 lb. with the sand, the figures becoming 2,841 and 1,241 respectively when the amount of soda was doubled. 2.5 per cent. of common salt gave a strength of 3,590 lb., and 932 lb. with neat and sand test-pieces.

The third paper was by W. Smith on "The Influence of Sea Water upon Portland Cement Mortar, and Concrete." The author recounts the nature of the damage done at Aberdeen, where a failure of concrete work occurred some years ago which has been the immediate cause of the anxiety that has been displayed in this country, both as to the effect of the presence of magnesia in Portland cement, and that of the action of the sea on its chemical and mechanical stability. The matter was reported upon by the late Prof. Brazier. The deduction drawn by engineers from this case and others is that it is of paramount importance to make concrete structures exposed to flowing water, and in particular sea water, impervious, so that in- and out-percolation may not take place and produce the destructive effects that have been observed when this condition has not been fulfilled. Accordingly the author carried out some experiments to ascertain what was the permeability of concrete mixed in different proportions. The apparatus shown in the Figure was

APPARATUS FOR TESTING THE PERMEABILITY OF CONCRETE.

used. It consists of a cast-iron box in which to mould and contain a cubic foot of concrete. It is provided with a conical bottom, ending in a square pipe, and is fitted with a water-tight cover, having a socket for the reception of the end of the pressure pipe connected with an overhead tank 21 ft. above the top of the block of concrete, and containing sea water. The results of the experiments, which are given in the form of an appendix at too great length to transcribe, show that to obtain an impermeable concrete (1) the cement must be finely ground, leakage occurring with a cement that left a residue of 10 per cent. on a 2,500-mesh sieve, while one that left only 2.5 per cent. on a 5,800-mesh sieve, made up in the same way was much less pervious. Coarse Roman cement was also very far from impermeable. (2.) That the cement should not be present in a smaller proportion than 1 to 6 of sand and stones. (3.) That the concrete should have sufficient time (at least three months) to set before the application of the pressure. If any of these conditions are made less favourable to the impermeability of the concrete, the remainder must be altered in the opposite direction. The author emphasises the innocuousness of the quantity of magnesia

present in Portland cement of good quality, and with regard to that deposited by the double decomposition of the magnesium salts in the sea water with the cementitious lime compounds in the concrete, points out that the continuance of the reaction, and the consequent destruction of the work, can only take place where, on account of the influence of a head of water or the extreme porosity of the concrete, the sea water has constant access to it, and thus continually introduces fresh quantities of magnesium salts. The rate of hydration of magnesia has been determined by H. T. Jones of Aberdeen University, who found that in 24 hours it absorbed 36 per cent. of water, in 48 hours 38.74 per cent., and in nine days 44.3 per cent., theory demanding 45 per cent. calculated on the original magnesia, showing that the rate of hydration was more rapid than that of Portland cement. No information is given as to the temperature at which the magnesia had been burnt. Analyses are given of a sample of Roman cement containing 2.47 per cent. of "sulphuric acid," the quotation of the figures being apropos of the alleged effect of quantities of sulphuric anhydride of this order of magnitude on the stability of cement concrete. In this instance no ill effects could be traced to its presence.

Dealing with preventive and remedial measures, the author demonstrates the futility of trusting to the impermeability of a film of calcium carbonate on the concrete, whether produced by exposure to air or more rapidly by washing the blocks with a solution of ammonium carbonate, as this is not sufficient to resist the entrance of sea water under pressure. He considers that the exclusion of the water by a film of Portland cement mortar cannot be permanently effective. Any accidental imperfection in the impervious coating will admit water and allow the destruction of the concrete beneath it. A lining of fine concrete 2-3 feet thick is more satisfactory, but again mischief may arise from the penetration of sea water through accidental openings to the porous hearting of the work. He concludes that the only certain way of building large masses of concrete or masonry for immersion in sea water under variable pressure, is to make the entire mass impermeable. It then becomes a question of expense whether Portland cement concrete may be more suitable for any work in sea water than masonry. Taking local prices (Aberdeen), he estimates the cost per cubic yard of the former at 11.0s. 2d., and of the latter, using cement mortar, at 19s. 8d. The forcing out of place of massive blocks of concrete may be traced in some cases to the presence of cavities in the work, which allow of sudden compression of the air in them by the waves and subsequent release, the action being purely mechanical, but sufficiently vigorous to eject blocks whose adhesion has been weakened by previous chemical decomposition.

A lengthy discussion on the three papers took place, certain portions of which are suitable for abstraction. H. Hayter endorses the necessity of adopting the determination of the specific gravity of cement in place of that of the weight per bushel. He quotes the case of the destruction of concrete at Belfast, in which analysis showed that the creamy deposit found in the damaged portions contained 80 per cent. of magnesium hydrate, and draws attention to the utility of the Deval hot test for excess of lime (this Journal, 1891, 255). L. Williams points out that as a rule Thames and Medway cements are to be preferred to those from the North country. T. Pevan mentions a case of a sample of cement weighing 112 lb. per bushel when shipped, and only 102 lb. on its arrival in the interior of Australia. E. W. Young contributes some figures obtained in testing cement at Cockatoo Island, New South Wales, in which the effect of a long sea voyage in lowering the specific gravity is evident. The highest observed was 3.15 and the lowest 2.63 (*sic*), while the mean was 3.075. H. Faija demurs to the supposition that magnesia in cement can be regarded as a passive diluent, and is of opinion that it should be regarded as so much lime. An instance of the decomposition of blue lias lime by sea water is given by C. Harrison. At West Hartlepool, concrete composed of 1.5 parts of blue lias lime, 1.5 of clean sand, and 0.5 of forge clinders was used for the construction of dock walls and entrance locks. After being in place for seven years from the time when water was admitted to the docks, the

whole of the mortar below high water-mark was found to have become soft. Commenting on this, J. W. Barry observes that such failures are due to the omission of thorough slaking of the hydraulic lime before use. At Barry Docks the lime, after having been drawn from the kilns, was completely wetted in sheds, and covered up with sand for not less than seven nor more than 14 days before being used. H. C. Seddon mentions an instance of the decomposition of concrete by ferruginous water, which percolated through comparatively porous mixtures, and in so doing became coloured green (due to the presence of ferrous sulphide), and contained sulphuretted hydrogen.

In the correspondence upon the papers the following views are worth recording. W. Sowerby states that in India certain lime nodules, supposed to be remnants of broken up coral reefs, are calcined, mixed with burnt clay, calcined ironstone and sand in about equal proportions, and incorporated in a mortar mill, the mixture serving as hydraulic mortar. The same purpose has been served by mixing calcined iron ore with lime. In Madras, where shells are used as the raw material for mortar, coarse sugar is added with good effect (this Journal, 1889, 545).

W. Matthews suggests the precipitated calcium carbonate produced by the Clark process for softening water, as a raw material for cement. P. J. Neate contributes the following figures for the expenditure of energy in grinding clinker. Taking the specific heat of cement as 0.155, a ton of cement raised in temperature by grinding from 60° to 200° F., would require the expenditure of 37,500,000 ft. lb. A pair of mill stones, 4.5 ft. in diameter and running at 140 revolutions per minute, would grind 25 cwt. of cement per hour and absorb 40 I.H.P., of which 23.7 horse-power would, from the above calculation, appear as sensible heat in the cement. A better result has been obtained with a large four-runner mill, having all its runners acting on the same inclined path in succession, 14 horse-power being used, and the cement delivered at a temperature of 70° F. The thermal economy of a cement kiln is considered by B. H. Thwaite. Taking the specific heat of the raw materials as 0.18, and the clinkering temperature as 3,000° F., the theoretical expenditure of heat necessary to raise them to this temperature is 1,209,600 heat units. The actual expenditure is from five to 10 times as much, so that the degree of economy is very poor. H. K. G. Bamber gives a table showing the decrease of specific gravity of cement on keeping, but as no information is given as to the conditions of exposure of the samples to the air, no end can be served by quoting it. W. G. Margetts has experimented with the Deval hot test (this Journal, 1891, 255), but has adopted the boiling point of water in place of 80° C. (176° F.) prescribed by its originator, and endorses the results obtained by him. H. N. Draper recalls the work of Le Chatelier (this Journal, 1888, 567, 847), and from the results arrived at by the French chemist, calculates that the theoretical quantity of water for the complete hydration of the tri-calcium silicate and tri-calcium aluminate present in a sample of cement of normal composition, is 41 per cent., an amount greatly in excess of that generally used in gauging test briquettes. The supposed disintegration of concrete exposed to sea water by the expansion of the magnesium hydrate resulting from the double decomposition between the lime compounds in the cement and the magnesium salts in the water, is proved to have no foundation in fact from the following considerations. The specific gravity of freshly formed calcium hydrate is 2.12, and that of freshly formed magnesium hydrate in its bulkiest form 1.65, and so far the figures favour the above-mentioned theory. But the molecular weight of calcium hydrate is 74, and that of magnesium hydrate 58, whence it follows that the space occupied by one molecule of magnesium hydrate is to that occupied by one molecule of calcium hydrate as 35.14 is to 34.8. As magnesium hydrate may exist in denser forms, e.g., as brucite, sp. gr. 2.35, it is possible that it may occupy even less space relative to that taken by the lime. W. F. Reid insists upon the necessity of drying turpentine to be used for taking the specific gravity of cement by allowing it to stand over fresh Portland cement before use, and also on the futility of giving the percentage of total

silica only in a clay when it is to be employed for cement making, as it is of importance to know what proportion is present as sand. Japp's volumeter (this Journal, 1891, 1029) or Lunge's new nitrometer (this Journal, 1891, 1031; also 1892, 1033) is preferable to the older calcimeters for testing the slurry for its percentage of calcium carbonate. The addition of salt to concrete to allow of work being carried on at low temperatures, is not advisable, as it sometimes leads to the deterioration of the cement. The mixture of crushed limestone with concrete has been known to hinder the action of sea water upon it. A criticism that may be urged to the experiments of H. T. Jones, upon the absorption of water by magnesia, is that the hydraulic properties of that substance depend wholly upon the temperature at which it has been calcined. At the clinkering temperature of cement it becomes almost devoid of hydraulic properties, and absorbs water very slowly. The apparent strength of a concrete mixture must always be considered in the light of the fact that, on account of its coarse grinding, English cement contains only about 50 per cent. of matter that has cementitious properties, so that a nominal 1:8 mixture is really only about 1:16. R. Feret, commenting on Bamber's assertion that the lime in the cement acts upon the silica of the sand grains with which it is mixed, remarks that actual experiment and observation of the grains of quartz embedded in Portland cement mortar, prove that they remain quite unattacked, and that the alleged action does not take place. He gives the results of experiments in which the portions of cement removable by sifting through a sieve of 5,800 meshes per square inch and through one of 32,300 meshes per square inch were replaced by an equal amount of sand, which shows that, except in the case of neat cement, the substitution of sand for the coarser cement does not decrease its strength, while even with the finer cement the decrease in compressional strength is not proportional to the amount of undoubtedly inert matter substituted, and the tensile strength is even slightly higher when sand is used in place of the comparatively coarse cement. The results bear out Reid's statement that about half the weight of English cement is practically inert on account of its coarseness. The most economical degree of fineness is indicated by the work of the same author, recorded in *Annales des Ponts et Chaussées*, 6, 19, 346. There is for any given mixture of a definite cement and sand, a proportion of water which gives the greatest strength, and another somewhat in excess of this which gives the most plastic consistency. The same relation holds good for maximum impermeability. A table, too voluminous to transcribe, contains the results of experiments on which these statements are based. W. Kidd, dealing with the cost of fine grinding, concludes that an extra cost of 3s. per ton in grinding only adds 8d. to the cost of a cubic yard of 5:1 concrete, while increasing the strength of the mortar about 50 per cent. As the eight pennyworth of cement is only half a cubic foot, or about 10 per cent. of the total amount used, a reduction of the quantity of cement might be made to this extent, and still give a stronger concrete than the coarser cheaper cement. C. Colson raises the question of the size of the wire of which the sieves for testing the fineness of cement are made. Strictly, the size of the wire must be specified as well as the number of meshes per square inch. Standard sand must not only be sized but washed with hydrochloric acid to free it from calcareous matter, which tends to raise the strength of the cement tested with it. The injurious action of oils upon cement is mentioned by Dyckerhoff. The addition of slaked lime to Portland cement helps it to withstand the action of sea water. The experience of M. Fitzmaurice in the building of the Chignecto Ship Railway in Nova Scotia, leads to the belief that concrete can be made and used in severely cold weather, provided that it is mixed under cover, and is kept thawed by the use of jets of steam and similar means at the time of its being put into place. If these precautions be disregarded, the concrete will not set and harden at all, even after the frost has ceased. W. Shield, trying the effect of exposing test-pieces of cement to the action of boiling water, finds that well aerated cement, such as that which is slightly caked at the surface of a heap, does not crack, while those

made from cement from the heart of the same heap fail, pointing to the need for aeration on a large scale to avoid the evil effects of underburnt and overlimed cements.—B. B.

The Building Stones of Great Britain. T. H. Beare.
Proc. Inst. Civil Eng. 107, Session 1891—92.

THE following data for the stones examined were ascertained. Crushing strength, density (by which is meant apparent density, as determined by weighing a block of known size, as opposed to true specific gravity), absorptive power, effects of low temperature, and alteration of the modulus of elasticity with increasing pressure. The experiments were made on 2½-in. cubes, as larger specimens could not, by the testing machine available, be crushed. The test-pieces were cut at the quarries whence they came, and were allowed to become air-dry in the laboratory before being tested, to allow the quarry-water to evaporate. The pressure was applied, unless expressly stated to the contrary, perpendicular to the planes of the quarry bedding, an important difference in the capability of the stone to resist weathering dependent on the preservation of this position, leading builders to take care that it is laid with its surfaces in this direction. The surface of the stone in contact with the dies of the testing machine was covered with a thin film of plaster of Paris to ensure even bedding. The use of compressible material such as sheet lead and soft wood in place of the plaster of Paris, was eschewed, as it was found that the lateral flow of such materials under the crushing strain produced tensile strains in the test-pieces, and induced their fracture at a smaller load than would otherwise have been the case. Proof of the existence of this influence was afforded both by the actual crushing loads of test-pieces which had been mounted in this manner, and by the character of their fracture, which departed from the ideal one consisting of six pyramids with their apices in the centre of the cube, and became that of a series of prisms parallel to the axis of pressure. The adverse effect of the presence of a sheet of lead ranged from 35.5 per cent. to 52.6 per cent. calculated on the strength determined without the use of lead, the difference being, as was to be expected, greatest in the case of the hardest stones, that is to say, when the total load was greatest. The result is of much practical importance, as illustrating the serious decrease in resistance to crushing strains that may be caused by bad bedding in structures. The mean crushing strengths in tons per square foot for the various classes of stones tested are as follows:—Granite, 1112.2 tons, mean of 13 varieties and 49 samples; oolites, 141.3 tons, mean of 18 varieties, 57 samples; sandstones, 489.8 tons, mean of 25 varieties, 88 samples; dolomites, 500.5 tons, mean of 4 varieties, 16 samples. The results are, generally speaking, higher and more concordant than those of previous experimenters. The "density," as stated above, was really a translation of weight per cubic foot, the weight of a cubic foot of water being taken as unity, as no attempt was made to estimate the true volume of stone free from air and moisture, in the blocks that were measured and weighed. The amount of water absorbed was estimated by weighing the blocks before and after immersion, New River water being used for a few of the earlier tests, and distilled water for the later members of the series. Some slight action by the water was perceptible in the case of the oolites, the water in which they had been immersed being turbid, and containing a distinct sediment. The author is of opinion that the absorptive power of the specimens "must be a very good guide to the relative weathering power of stones, since it shows to what extent deleterious agents in rain water and fogs will penetrate the stone, and furthermore a very absorbent stone must be very liable to the destructive action of frost." The mean results were that the average absorption of 27 oolites was 8.96 per cent. of their dry weight; dolomites, 4 samples, 5.43 per cent.; sandstones, 26 samples, 4.68 per cent.; granites, 14 samples, 0.27 per cent.

Fig. 1 shows the relation between compressive strength and absorption of 10 samples of Bath stone. The specimen marked "Westwood (fluted)" has been treated with

Curve A, crushing strengths; Curve B, ditto, after immersion in water for seven days and re-drying. Curve C, percentage of water absorbed.

Kessler's preservative solution, which is said to have proved very successful in France in checking the decay of oolitic and other limestones. A few specimens were tested by exposure after saturation with water to the low temperature prevailing last winter, the temperature varying from 20° to 32° F. Thawing and freezing were alternated 10 to 12 times, and the cubes were afterwards left exposed to the rain and weather for some two or three weeks. The loss of weight of the granites by this treatment was inappreciable, while with the other stones it was quite small, amounting to 0.002 lb. as a maximum, the original weight of the cubes being about 1 lb. There was also no loss of strength. The determination of the modulus of elasticity was difficult, owing to the small quantities to be measured, and a special form of gear was devised by A. G. Ashcroft for the purpose, which multiplied the actual alteration in height 2,358 times. It was found that there was a comparatively large permanent set, and the figures for the test first made are therefore lower than those obtained in repeating the test when this factor had been eliminated. The mean value for all the sandstones tested was, for the first test, 108,040 tons per square foot, and for the second test 132,280 tons, corresponding to 1,680,600 and 2,057,700 lb. per square inch respectively,—about $\frac{1}{15}$ to $\frac{1}{27}$ the value for steel. The mean values for the magnesian limestones were 254,500 and 321,000 tons per square foot respectively. For limestones the figures are 133,530 and 150,750 tons, while for granites they were 479,009 and 522,100 tons, or about one quarter the modulus of elasticity of steel.

The following table gives a few typical figures selected from the results recorded by the author:—

Name of Stone.	Locality of Quarry.	Remarks.	Mean Crushing Load.	Weight.	Absorption.
				Per Cu. Ft.	Per Cent.
Sandstones.	Prudham	Hexham, Northumberland.	455.3	142.5	4.00 (4.33)
	Polmaise	Bannockburn	551.5	141.7	4.58
	Bamie	Lanlithgowshire	569.1	135.1	5.22
	Hermant	Middlethian	457.4	142.6	4.70
Dolomites.	Yellow magnesian limestone.	Mansfield Woodhouse Quarry.	577.4	145.4	4.62
	Auston	Kiveton Park, Sheffield.	301.9	132.2	7.50
Oolite.	Portland	Isle of Portland	287.0	137.6	6.84
Granites.	Kenmay	Aberdeenshire	1,088.5	164.1	0.42
	Bridge	Bridge	1,211.1	161.9	0.21
	Rubislaw	Aberdeen	1,098.8	163.7	0.09

PATENTS.

Improvements in Processes for making Plastic Compounds or Composition. J. U. Robertson, Willesden Green. From C. W. Kennedy, Philadelphia, U.S.A. Eng. Pat. 17,050, October 7, 1891.

WASTE products such as "salt hay, grass straw, reeds, rushes, common hay, leaves, twigs, husks," are utilised in their green or dried state. Wood chips, splinters, sawdust, hair, waste paper, junk and scraps of fibre, such as hemp, jute, flax, coir, &c., may also be employed. Long fibres of the latter class of material are placed in a tank with water, and "a quivering or vibratory" motion imparted to the mixture, causing the fibres to fall together. "Finely-powdered silica or lime cements" are added, though "glutinous (*sic*) cements may also be used if desired." Any suitable waste scraps are incorporated as filling and the mass taken from the tank and moulded by pressure. With the addition of sand and hydraulic cement, or by enclosure in a "frame of molten metal," or by coating with approximately equal parts of "gluten, gelatin, pitch,

resin, or silicates of sodium or potassium" and subsequent immersion in a bath of calcium chloride, the composition may be rendered fit for use as paving or flooring. The manufacture of artificial wood and railway sleepers, and the renovation of worn-out sleepers, are also among the purposes contemplated by the patentee.—B. B.

Making Coloured Stucco, Coloured Concrete Blocks, and Tiles. D. Ward, Hewton. Eng. Pat. 19,106, November 5, 1891.

THE patent is for "the mixing together of colours with cement or lime, sand, or rubble with water to form stucco, concrete blocks, or tiles of a permanent colour, as the colour will permeate the coloured mixture and when dry and hard will be imperishable."—B. B.

Improved Process for Producing Liquid Clay or Slip for Casting in Moulds. E. Edwards, London. From K. Goetz, Karlsbad, Bohemia. Eng. Pat. 15,911, September 5, 1892.

Slip, from which articles of porcelain or stoneware are to be prepared by casting in moulds, is mixed with "an aqueous solution of one of the bases of soda, potash, lithia, oxide of ammonium" or with an aqueous solution of "a carbonate or multicarbonate of three bases—but not including the carbonates of soda—as also the silicates and fluor salts of these bases." Three parts by weight of such a solution suffice for 100 parts by weight of clay. Cinnabar sufficient to give the solution a weak rose tint may be added to prevent the formation of a grey colour sometimes observed on porcelain after burning. The pateated mixture contains less water than is usually necessary, is said to cast better and allow the moulds to be used oftener and dried sooner. The cast articles may be burned at a lower temperature than is generally necessary, and the grinding of the slip takes 16 hours instead of 22 or 24 hours. Colours can readily be burned in.—B. B.

PATENTS.

Improvements in Adding Metallic and Non-Metallic Substances to Steel and Iron or any other Liquid Metals. J. Colley, Bilston. Eng. Pat. 18,990, November 4, 1891.

THE improvement consists in adding carbon, enclosed in a box or receptacle, preferably of wood, to the charge, after the blowing is completed, or nearly so, and before it leaves the furnace or converter. The carbon may be added all at once or in separate portions, and ferro-manganese may be added with it when necessary.—J. H. C.

A Process of Separating Cobalt from Nickel. G. Selve, Altema, Germany. Eng. Pat. 19,573, November 11, 1891.

COBALT is separated from nickel when in hydrochloric or sulphuric acid solution, after separation of other bodies by well-known methods, by adding to the solution a precipitating liquid prepared as follows:—

To an aqueous solution of hypochlorite of soda—composed of 100 kilos. of chloride of lime and soda, 60 kilos. of calcined soda dissolved in water are added. When the precipitated carbonate of lime has settled the liquid is drawn off for use. The cobalt and nickel solution is boiled and stirred and the precipitating liquid is slowly added until a sample shows that the whole of the cobalt is separated in the shape of a black deposit (of Co_3O_4), the nickel remaining in solution.

Small quantities of nickel oxide precipitated at the same time may be redissolved by means of dilute sulphuric or hydrochloric acid.—J. H. C.

Improvements in Gas Furnaces. H. E. Newton, London. From R. N. Oakman, jun., Greenfield, U.S.A. Eng. Pat. 21,634, December 10, 1891.

THE furnace described in this patent is adapted for heating pipes for welding the longitudinal seam, and also for heating iron or steel bars for forging and welding. The principal

objects aimed at are to ensure a uniform heating of the pipes, bars, or blooms, and to utilise the waste heat from the furnace.

The welding furnace chamber may be described as somewhat pear-shaped in longitudinal section. It is heated by a series of nozzle burners fixed in inlet flues which are built into the top of the narrower end of the furnace; these burners are fed with a mixture of fuel-gas and air, both of which are supplied under pressure. The flames and products of combustion first pass along the crown of the furnace; they are then deflected downwards by the arched crown and side, and are caused to pass over and in contact with the pipes, bars, or blooms, which are arranged on the hearth; finally they escape by a narrow outlet flue, placed parallel to and underneath the inlet flue, whence they pass into a second chamber. The advantage of this method of heating is that the outgoing flames or currents pass through the furnace chamber between the materials to be heated and the inflowing flames, so that the latter are not chilled by the cool pipes or other materials. As, moreover, the pipes, &c., are introduced into the furnace near the outlet flues and are then gradually moved along the hearth to the other end of the furnace, their temperature is gradually raised to a welding heat, whereupon they are withdrawn and welded in the usual manner.

The outlet flues for the gases from the welding chamber pass directly into a heat-restoring chamber, in which the skelp is raised to the requisite temperature for rolling; in order that the flame may be prevented from impinging upon the skelp the flues are made to incline upwards just before they enter the heat-restoring chamber.

The waste gases from the heat-restoring chamber are finally passed into a second chamber, in which the air necessary for the combustion of the fuel gas is heated.

—F. S. K.

Improvements in Gas Puddling Furnaces. H. E. Newton, London. From R. N. Oakman, jun., Greenfield, Mass., U.S.A. Eng. Pat. 21,633, December 10, 1891.

THE claim is for a double-hearth furnace consisting of two separately-heated chambers with curved walls communicating with each other by an inclined or tangential flue, and each supplied with a valved escape flue. The heating is effected by the combustion of gas and air introduced near the crown of the chambers or furnace, and under pressure. The waste gases from the working operations in the first chamber are used for heating up the second, and thence pass to a heater where they are used for heating the air blast which supplies the burners.—J. H. C.

Improvements in the Manufacture of Ingots, Bars, Rods, Wire, and the like from Bronze. G. G. M. Hardingham, London. From C. Berg, Eveking, Westphalia, Germany. Eng. Pat. 22,337, December 21, 1891.

COMPOUND ingots for electrical conductors and similar purposes are made by casting soft bronze projections or coverings around hard bronze cores and *vice versa*, or the combinations may be threefold, and of brass, copper, aluminium, or other alloys and metals. The contact surfaces are formed with ribs or projections, to facilitate the uniting or welding.—J. H. C.

Improvements in or relating to the Purification of Steel or of Iron during its Conversion into Steel. E. H. Saniter, Wigan. Eng. Pat. 8,612, January 21, 1892.

IRON is purified from sulphur during its conversion into steel by adding, while it is molten and in the furnace, a mixture of chloride or fluoride of an alkaline earth with the oxide, hydrate, or carbonate of an alkaline earth; the latter in sufficient quantity to form and maintain a slag having from 50 to 60 per cent. of lime.

Chloride of calcium and limestone are recommended in general, but other corresponding substances may be used in special cases.—J. H. C.

Improvements in or relating to the Purification of Iron.
E. H. Saniter, Wigan. Eng. Pat. 8612x, January 21, 1892.

THE molten iron is brought into sufficiently prolonged contact with a mixture of chloride of calcium and lime, or their chemical equivalents.—J. H. C.

Improvement in the Means for Tempering and Hardening Metals. J. S. Darning, Emsworth, Pa., U.S.A. Eng. Pat. 12,965, July 14, 1892.

THE metals are first coated with a mixture of flour, prussiate of potash, and a liquid concoction from the laurel plant; then heated and plunged into water or into a similar liquid concoction.—J. H. C.

Improvements in the Process of Reducing Unsmelted Ore, including Roasted Ore, Furnace Cinders, and like Material. J. T. Wainwright, Chicago, U.S.A. Eng. Pat. 16,17x, September 9, 1892.

THE improvement consists in operating on the ores by generating gases at successively increasing temperatures, passing these gases downward through the ore, and maintaining it in an unreplenished condition.

In general a shaft furnace is used, having a collecting space or slag hearth at the bottom, and an inverted siphon outlet or gas flue at the side. The furnace is fed from the top through an aperture which is then securely closed, intermittent heats being made, and the furnace re-charged for each heat. Operating on iron ore, and commencing with an empty furnace, the lower contracted portion of the furnace is bridged over with an open mass of charcoal or other solid carbonaceous fuel. On top of this is placed a charge of mixed ore, flux, and fuel, in suitable proportions, and above this carbonaceous fuel, which may be cheaper or different in grade to that charged with the ore, and may be mixed with suitable flux. A hot or cold blast of air or other gases containing free oxygen is then thrown on the top of the ignited fuel layer, the cover is closed, and the blast is maintained. The gases resulting from the fuel combustion are forced downwards through the mixed charge and fuel, so producing a gradually increasing temperature which, besides facilitating reduction, prevents scaffolding and congestion.

The effect produced upon the ore by forcing the gases downwards through it is to maintain a reducing action, and also to keep the upper parts of the ore-charge in a hotter and more reduced condition than those below; consequently, when the reducing action reaches that stage when the cinder separates from the spongy metal and gravitates from the same, this isolation of the metal will progress from above downwards, so that the slag will collect in the hearth without having been in contact with the metal at a high temperature. In this way the impurities of the ore remain in the cinder, and do not contaminate the metal. When the slag is more fusible than the metal it may be drawn off at an early stage through a tap-hole, after which the blast may be continued for the purpose of maintaining the temperature of the metal which has collected in the hearth, and also for scouring the shaft. In other cases, the metal, being more fusible, may be run out first, and the slag afterwards run out at a higher temperature.

To facilitate working, the hearth may have a series of tap-holes at different heights, and also a large opening with a cover at the side, through which fuel, fluxes, or metals for alloy may be added in certain cases.

Another mode of operation is to use two shafts placed side by side and communicating at the top. The first is charged with cheap solid fuel and used with an upward draught as a gas producer; and from this the ignited gases pass into the second and downwards through the ore-charge, as already described.—J. H. C.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

The Influence of Arsenic, Antimony, and Silicon on the Ductility, Absolute Strength, and Electrical Conductivity of Copper. W. Hampe. Chem. Zeit. 16, 726–728.

THE pure copper employed by the author was prepared by adding caustic potash to copper sulphate solution until a considerable precipitate was obtained; the solution was then heated for some time, filtered, and the filtrate electrolysed. The deposited copper, after treatment with boiling water and repeated washing, was dried and fused with copper oxide, first in a current of carbon dioxide, whereby any residual copper sulphate is dissociated and the sulphur expelled as SO_2 , and finally in a stream of dry hydrogen, whereby any oxide is reduced to metal. The copper so obtained contains no impurity beyond traces of antimony.

Pure arsenic is prepared by adding ammonia and magnesia mixture to potassium arsenate solution; the precipitated ammonium magnesium arsenate is filtered off, washed, dissolved in hydrochloric acid, and re-precipitated by ammonia. After washing, the precipitate is converted into magnesium pyro-arsenate by heating; pure arsenic sublimes from this salt on heating it in a stream of hydrogen. Pure antimony is prepared by heating an intimate mixture of tartar emetic (5–6 pts.) and nitre (1 pt.) in a porcelain crucible. The residual antimony is washed with water and fused in a current of hydrogen.

An alloy of silicon and copper (silicon-copper) has been previously prepared by the author by heating a mixture of silica, fluorspar, purified lampblack, and copper in the proportions required by the equation—

The yield of silicon in the alloy is frequently only one-half of that indicated by the equation, and is not appreciably increased by the employment of more silica. Practically, no reduction of silicon occurs if carbon be excluded from the mixture. Silicon copper is not obtained by heating copper in a stream of hydrogen containing silicon tetrafluoride. On melting a mixture of fluorspar and silica, silicon tetrafluoride is at once obtained—

The alloys were prepared by fusing the pure copper with arsenic, antimony, or silicon copper, in a closed crucible under a layer of lampblack free from manganese. The following table gives the absolute strengths, relative conductivities, and densities of the various alloys examined:—

		Absolute Strength per 1 sq. mm. cross-sectional Area.	Relative Conductivity.	Density.
Pure copper.....		Kilos. 31'6	100	8'9565
Alloy I. containing 0'2161 per cent. As		41'6	61'05	8'944
" II. " 0'351 " "		51'1	50'15	8'947
" III. " 0'808 " "		48'9	29'96	8'962
" IV. " 0'260 " Sb		52'0	68'67	8'948
" V. " 0'529 " "		54'9	56'5	8'946
" VI. " 0'526 " Si		50'0	28'11	8'870
" VII. " 3'472 " "		95'3	6'5	8'471

The ductility of the alloys was about the same as that of pure copper with the exception of sample No. III., which was somewhat less ductile. The toughness and ductility of copper seems hence to be little affected by the presence of very appreciable quantities of arsenic or antimony.

The sample No. VI. of silicon copper resembles pure copper in appearance and properties.

When the percentage of silicon reaches 1.5–2.0 the metal has a reddish-yellow colour, and, though still ductile, is harder than pure copper. Sample No. VII. has almost the composition Cu_2Si , possesses a light bronze colour, and a glistening fracture; it is very ductile and malleable. Copper containing 6 per cent. of silicon shows a light grey crystalline fracture, is hard and brittle, and dissolves completely in nitric acid; the solution gelatinises when concentrated. An alloy containing 8 per cent. of silicon is silver-white and very brittle; it may be readily crushed to powder. Copper containing 11.7 per cent. of silicon is as brittle as glass; it is white in colour and rapidly tarnishes brown in the air. It is almost completely soluble in nitric acid.—W. J. P.

PATENTS.

Improvements in Apparatus for Use in Electro-Metallurgical Operations. C. Hoepfner, Giessen, Germany. Eng. Pat. 13,735, September 1, 1890. (Amended.) (This Journal, 1891, 839.)

THE inventor wishes it to be understood that he does not claim anything which is described or claimed in Eng. Pat. 12,208 of 1888.—J. C. C.

An Improved Process for the Electro-Deposition of Metal upon the Surface of Glass, Porcelain, China, Earthenware, and other Materials. A. S. Ford, London. From H. Pottier, Paris. Eng. Pat. 18,256, October 23, 1891.

See under VIII., page 1007.

A Depolarising Liquid for Galvanic Batteries. O. Schlesinger, Bow, Middlesex. Eng. Pat. 18,477, October 27, 1891.

THIS liquid is for use in two-fluid cells and consists mainly of a sulphuric acid solution, crystals of chromic acid, and nitrous acid solution. The following is a suitable example of making up the liquid: 20 oz. of sulphuric acid (1.8 specific gravity) are diluted with 11 oz. of water, and, while the solution is still hot, from 2 to 3 oz. of chromic acid crystals and from 15 to 25 oz. of nitrous acid solution (sp. gr. about 1.360) are added. The mixture is ready for use when cool. If the carbons of a zinc-carbon battery are immersed in such a solution, and the zincs immersed in water or acidulated water, the current developed is of great constancy. The liquid may be used in gutta-percha cells without injury to the cells.—D. E. J.

Improvements Relating to the Application of Depolarisers in Electrolysis. J. C. Richardson, London. Eng. Pat. 19,704, November 13, 1891.

THE object of this invention is to maintain the depolarising action of a compound, such as an insoluble oxide, next the cathode in electrolytic work. The cathode consists of a broad band of any desired construction and surface, upon which as it enters the electrolyte a depolariser is introduced, and as it leaves, the spent depolariser is removed; or instead of the cathode itself moving, the depolariser may be made to move on it. This patent is adapted to the process described in Eng. Pat. 2,296, 1890 (this Journal, 1891, 699), in which oxide of copper is employed in the electrolysis of salt; the oxide of copper in this case being introduced next the cathode at one point, and the reduced copper being removed at another.—G. H. R.

Improvements in and relating to the Construction of Electrodes of Large Dimensions for Accumulators, and to supporting the same in their Cells. W. P. Thompson, Liverpool. From A. V. Kerekhove, Brussels, Belgium. Eng. Pat. 21,702, December 11, 1891.

THE invention consists in the adaptation of electrodes of normal dimensions to cases or rigid gratings so constructed as not easily to be put out of shape, and which are neutral as regards their chemical reactions. The normal electrodes are arranged in successive cases of the frame, and soldered at two points by one of their sides in such a way as to preserve between their three other sides and the cross bars of the frame a sufficient space to allow of dilation and extension. Small projections on the opposite sides of the edges of the plate or of the cross-bars of the frame, and cast thereon, at the same time prevent the electrodes from becoming displaced during working. The squares, gratings, or frame may be of any suitable form and composed of any suitable material which offers sufficient rigidity, conductivity, and neutrality to the action of electrolysis. Large electrodes are allowed to rest at a greater or smaller number of points throughout their entire length on strips of glass, ebonite, or any other insulating material, or even on a series of insulating pegs or wedges arranged in the same plane; the strips or wedges are placed in the bottom of the cells, and are of a height corresponding to the space which it is desired to leave free between the bottom of the cells and the lower edges of the electrodes.—G. H. R.

Improvements in and Apparatus for the Manufacture of Alkaline or Earthy Alkaline Bases and of their Salts or Compounds by the Electrolysis of Saline Solutions. E. Hermite and A. Duboseq, Paris. Eng. Pat. 21,957 December 15, 1891.

"It is known that when an electric current is passed through a solution of any salt of any alkaline or earthy alkaline base, the acid and oxygen pass to the positive pole and the metal passes to the negative pole." It has been proposed to utilise this principle for the purpose of separating the alkalis and bases of the alkaline earths (for example, potash and caustic soda), from their compounds, but in order to do so it is necessary to provide some means of at once removing the separated base from the acid to prevent re-combination. Two methods have been adopted to do this, of which the first was abandoned. In the second method mercury is employed as the negative pole, which forms an amalgam with the deposited metal. It is, however, necessary to devise some means of removing the amalgam thus formed, as otherwise re-combination will take place and the energy of the current will be expended uselessly. The object of the present invention is to provide such a means. The inventors describe the principle of their arrangement by reference to an ideal electrolytic cell impossible to realise in practice. In this imaginary cell the negative pole is of mercury floating on the surface of the electrolyte, the positive pole being at the bottom of the vessel. Floating on the mercury is pure water. Suppose the electrolyte be a solution of a sodium salt. When the current passes, an amalgam is formed at the surface of the mercury, which, being lighter than the mercury, rises to the surface of the latter, where it comes into contact with the water and is decomposed into caustic soda and mercury, the soda remaining in solution. Such a cell, if it could be constructed, would be all that is required, and it is to a means capable of realising the conditions of this theoretical arrangement that the invention relates.

The new arrangement is as follows:—Mercury is made to drop from a suitable tank through a series of fine tubes on to two inclined iron plates which form the negative pole. The object of the tubes is to distribute the mercury in a thin flat sheet over the surface of the plates, which are amalgamated to ensure an even flow of the mercury, which would otherwise roll down in globules. The positive pole consists of two plates of platinum parallel and very close to the iron plates. When the current passes an amalgam is formed which flows to the bottom of the iron plates into a suitable trough containing bisulphide of carbon or other

liquid lighter than the amalgam and denser than the electrolyte, which screens it from the action of the acid. Now an amalgam of mercury and another metal becomes lighter in proportion as it contains more of the metal. Hence the mercury containing little of the metal sinks to the bottom of the trough and is discharged through a tube into a reservoir. The richer amalgam rises to the top of the trough and passes through a suitably-placed tube into a cistern of water, where it is decomposed into the base and mercury. The base remains in solution, while the pure mercury sinks to the bottom of the cistern and passes into the reservoir. From the reservoir it is lifted by means of any suitable elevator (such as a series of buckets on an endless rope) and returned to the distributing tank to be discharged once more on to the negative plates.—D. E. J.

Improved Jar or Cell for Galvanic Batteries. W. P. Thompson, Liverpool. From O. Hirsch, Weiswasser, Germany. Eng. Pat. 22,145, December 18, 1891.

In battery jars hitherto employed it has been necessary to adopt special devices for the purpose of securely insulating the two electrodes from one another, such as, for instance, the insertion of special porcelain pieces between zinc and carbon, which were firmly retained in their places by india-rubber bands. Such bands, however, rotted away, and moreover, crystals were deposited on the porcelain pieces. Various attempts to remove these drawbacks have been made by forming on the square jar an almost circular projection connected with the remaining space only by a narrow opening, into which projection would be inserted the zinc bar. Such cells are both inconvenient and costly, and have therefore not been much used. This invention relates to a glass jar or cell having none of the above drawbacks. The cell is square in form, and while in a semi-fluid condition, impressions, projecting towards the inside of the cell, are made at a suitable distance from the corner destined to receive the zinc bar, which serve to enclose the zinc bar and prevent all possibility of its coming into contact with the carbon plate.—D. E. J.

Improvements in the Manufacture of Porous Carbon for Batteries and for Filters. W. Hellesen, Copenhagen. Eng. Pat. 22,708, December 29, 1891.

This invention relates to a method of manufacturing porous carbon suitable for batteries and filters. To increase the porosity of the carbon for galvanic batteries, it has been the custom to mix with it such organic substances as sawdust, fat, flour, or the like. For filtering carbons, the carbon-producing substances have been mixed with clay, finely-divided silica, or the like. It has been recently proposed to use a mixture of lignite, clay, and chaff. The inventor has found that infusorial earth mingled with hydrocarbon-yielding substances, such as tar, produces when highly heated a more efficacious porous carbon than any of the mixtures above referred to, and which is suitable both for batteries and for filters, with or without the addition of graphite or of animal substances. A satisfactory mixture may be composed as follows:—40 to 50 parts of infusorial earth, the same quantity of coal-tar or some similar hydrocarbon-containing material, and 5 to 10 parts of horn or some similar substance. If graphite is to be added the quantity of infusorial earth must be reduced.—D. E. J.

Improvements in Secondary Batteries. W. Main, Brooklyn, U.S.A. Eng. Pat. 16,461, February 15, 1892.

In this cell the positive electrodes consist of vertical compound plates formed of thin sheets of lead, and the room necessary for the increase of thickness of the plates due to oxidation is provided by coating the thin sheets with a soluble material which is afterwards dissolved out. The material preferred for this purpose is a mixture of oxide of zinc and graphite, as the former dissolves during charge and yields a deposit of zinc on the negatives where it is required.

The negative electrodes are U-shaped perforated sheets of copper amalgamated with mercury and plated with zinc. Sheets of zinc are placed between each pair of copper plates to maintain the supply.—G. H. R.

Improvements in the Means for and Method of Melting Metals and other Materials by Electricity. A. F. W. Kreinsen, Ottensen, Germany. Eng. Pat. 15,477, August 29, 1892.

ACCORDING to these improvements, the fusion of the material is effected in electrically heated carbon or plumbago crucibles consisting of insulated or non-insulated pots, surrounded by platinum conductors, or it may be primarily fused by being brought into contact with a carbon electrode through which a sufficient electric current is caused to pass. The material to be melted forms the negative electrode. Both of the electrodes are moveable and adjustable so that they may be moved towards or withdrawn from each other as may be required. They are arranged above the centre of the crucible, and are covered by a shield to prevent the escape of sparks and splashes from the fusing material, which drops into the cavity of the crucible, and is there either re-melted or kept in a state of fusion by the heat generated by the passage of a shunted portion of the current through a spiral of platinum wire embedded in the walls of the crucible, or the crucible may have an outer lining of very thin platinum similarly maintained at a high temperature.—G. H. R.

An Improvement in Galvanic Batteries. E. Nunau and J. W. Nelson, London. Eng. Pat. 15,739, September 2, 1892.

THIS is a zinc carbon battery, the zinc forming the outer case of the cell. The carbon is partially coated with tin foil and is embedded in a mixture consisting of the following ingredients:—

	Parts.
Pulverised carbon.....	35
Pulverised peroxide of manganese.....	30
Sal ammoniac.....	10
Chloride of zinc, or analogous material that has the power of readily absorbing moisture from the atmosphere.....	1
Water.....	20

The zinc cylinder is lined with a compound prepared as follows:—

	Parts.
Chloride of zinc.....	10
Sal ammoniac.....	10
Plaster of Paris.....	30
Water.....	20
Starch or flour.....	$\frac{5}{16}$
Pulverised alum.....	$\frac{1}{16}$

which are poured in after the coated carbon has been placed in position. Suitable means are provided for making contact, and the cell is closed with a mixture of Egyptian pitch and plaster of Paris.—G. H. R.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

PATENTS.

An Improvement in what is commonly called Dry Soap or Soap-Powder and intended for Use for certain Purposes. W. H. Horton, Bowden, and E. M. Taylor, Prestwich. Eng. Pat. 16,018, September 7, 1892.

A SUITABLE quantity of "blueing powder" such as "Reckitt's blue" is incorporated with ordinary soap powder with a view to enable articles to be washed and blued in one operation.—K. E. M.

Improvements in and relating to Apparatus for Expressing Liquids from Vegetable, Animal, or Mineral Substances. H. H. Lake, London. From La Société Anonyme du Compresseur Jourdan, Paris. Eng. Pat. 17,886. October 19, 1891.

WITH the view of dispensing with bags or sacks for extracting purposes, the inventor makes use of an apparatus essentially characterised by the employment of removeable or non-removeable tubes constituting channels in the thickness of the walls of the cylinder of the compressor, one of the faces of each tube being provided with saw cuts, and covered by joining wires of any section between which the liquid, resulting from the compression of the material, filters. A filter cloth in certain cases may be placed between the wires and the exterior surface of the outflow tube, or channel. In combination with this a preparatory press serves as a lifter, and has two small pistons, one at the top and the other at the bottom of the apparatus for the introduction of the material, and a third piston of larger diameter for its removal. The cylinder is provided with wheels to render it portable.—J. C. C.

Improvements in Candles and Night-Lights. F. G. Griffith, Cowbridge. Eng. Pat. 21,378, December 7, 1891.

IN order to prevent any waste in the burning of a candle, each candle contains a cup-shaped socket at the end, which has a tube surrounding the wick. This tube extends to the top of the socket and has a slit down one side. When, therefore, the candle is burned down to the socket the remaining part will burn as an ordinary night light till all the grease is consumed.—K. E. M.

XIII.—PAINTS, PIGMENTS, VARNISHES, RESINS, INDIA-RUBBER, Etc.

Manganese Borate, its Constitution and Properties. W. N. Hartley and H. Ramage. Proc. Chem. Soc. 116, 201—202.

PARTICULARS are given of the properties of manganese borate, prepared in various ways from manganese sulphate and alkaline borates. Manganese borate dried *in vacuo* over sulphuric acid is found to lose water to the extent of 11.84 per cent. of its weight when heated at 100°; when heated from 100° to redness, it loses 19.65 per cent., which is water of constitution, the compound being a tetrahydric orthoborate, thus:—

The solubility of manganese borate in various saline solutions was investigated: it was found to possess a maximum solubility at or about 18°, and a minimum at 80°, so that when cold saturated solutions are heated, they deposit the salt at the latter temperature.

It is believed that this is caused by the dehydration of the salt in solution, namely, $\text{MnH}_3(\text{BO}_3)_2 \cdot \text{H}_2\text{O}$, which becomes $\text{MnF}_4(\text{BO}_3)_2$, and this, being less soluble, is deposited: such a change being known to occur, and to be complete at 100° when the salt is heated in air.

PATENTS.

Improved Composition applicable as a Dressing for Belting and other Purposes. S. Kenyon, Warrington. Eng. Pat. 17,811, October 17, 1891.

REFUSE india-rubber or gutta-percha is incorporated by the aid of heat with vegetable tar, with or without the addition of varnish foots.—F. H. L.

Improvements in and relating to Paints and Lacquers. A. O. and W. S. Gill, Aberdeen. Eng. Pat. 22,610, December 28, 1891.

THIS patent refers specially to gold, silver, and bronze paints, as the varnish for which the inventors use collodion.—F. H. L.

Improvements in the Construction of Moulds for Vulcanising India-Rubber Tyres and other Rings. H. H. Waddington, Hyde, Chester. Eng. Pat. 10,171, May 28, 1892.

THESE moulds are built up by the super-position of a number of metal discs, having in their adjacent faces a series of semicircular annular grooves, in which the tyres to be vulcanised are placed, and having also a number of apertures through which the steam can circulate. The steam is prevented from reaching the tyres by the discs having smaller grooves running parallel with the larger, in which asbestos packing rings can be placed.—F. H. L.

An Improved Solvent for Gums and Resins, and Method of making the same. W. Read, Needham, Mass., U.S.A. Eng. Pat. 11,174, June 14, 1892.

EQUAL parts of coal-tar, naphtha, and petroleum-naphtha are taken, and about one-eighth of alcohol added. A precipitate consisting of the creosote oil and carbolic oil of the former and the dead oil of the latter is thrown down, and the clear spirit, which may be "deodorised" by a suitable essential oil, forms the improved solvent. The precipitate is valuable as it is suitable for use as an oil for dissolving gums.—F. H. L.

Improvements in and relating to the Manufacture of White Lead. A. J. Smith, Kingston-on-Thames. Eng. Pat. 14,656, August 13, 1892.

LEAD cuttings of suitable dimensions, after preparation by dipping in "basic cream," are placed upon trays or grids and inserted in the converting chamber, and there alternately subjected to the action of acid vapour, mixed with steam and atmospheric air, and to the action of carbonic acid gas; from time to time applying to the charge a spray of "basic cream" as occasion may require. The "basic cream" is prepared by digesting to the consistency of thin cream lead oxide in weak pyroligneous, acetic, or other suitable acid.—J. C. C.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

PATENTS.

Improvements in Apparatus or Appliances for Use in Drying Sheets of Glue, Gelatin, and the like. W. P. Thompson, Liverpool. From F. Krauseder and A. Lentsch, Munich, Germany. Eng. Pat. 20,755, November 28, 1891.

THE drying chamber is provided with adjustable trays having longitudinal strips upon which the sheets of glue, &c., to be dried, are placed. The trays are made thicker in cross section towards the exit end, and in consequence the air spaces are narrowed; by this means the speed of the air is accelerated as it is drawn through the apparatus by the fan and in consequence a uniform amount of evaporation takes place over the whole surface.—J. C. C.

A New Process for Tanning and Apparatus relating thereto. G. V. Haeclit and C. Obozinski, Brussels, Belgium. Eng. Pat. 21,774, December 12, 1891.

THE apparatus consists of a vat containing a perforated casing the lower part of which forms a false bottom to the vat; the lid of the vat fits air-tight and carries a pressure gauge, a vacuum gage, and an escape cock. Through openings in the sides of the vat pass pipes, provided with cocks and connected with a pressure pump, a vacuum pump, a high level tank for supplying liquor, and a low level tank for receiving liquor, respectively. An attached water-gauge indicates the level of liquid in the tank.

The skins are arranged in the perforated casing as follows:—a layer of wood-wool, previously impregnated with tannin, is placed on the bottom; a sheet of wool or other fabric, also impregnated with tannin, is spread upon the wood-wool; the skin to be tanned follows; on this is another sheet of wool and then another layer of wood-wool. This order of layers is repeated until the vat is full. The wood-wool forms a very porous material which serves to keep the layers apart, but to avoid unequal action of the tanning liquor due to the direct contact of the skin with the inequalities of the wood-wool, the sheet of fabric is interposed. When the vat is full of skins, the air in it, together with that in the pores of the skins, is pumped out by the vacuum pump. The tanning liquor is then allowed to flow in from the high level tank and pressure is applied by the pump for that purpose. After a sufficient time the liquor is allowed to run into the low level tank, whence it can be pumped into the high level tank, to be strengthened up or used again for a fresh batch of skins.—A. G. B.

XV.—MANURES, Etc.

Interaction of Ferrous Sulphate with the Phosphates of Calcium employed in Agriculture. P. Cazeneuve and A. Nicolle. Mont. Scient. May 1892, 334—337

SINCE the application of ferrous sulphate of "copperas" has been found advantageous in the case of the vine and certain other plants, it has become the custom of manufacturers of manures to mix this salt with the other ingredients of a manure, more especially in the case of phosphates. The object of this investigation was to ascertain whether the solubility of the phosphates is modified by the addition of ferrous sulphate in such a way as to render them less readily assimilated.

It was found that ferrous sulphate, which in contact with moist air is oxidised to ferric sulphate, does interact with some of the various phosphates of calcium which are employed in agriculture, bringing about the formation of

ferric phosphate; as the last-named compound is soluble in ammonium citrate, and slightly soluble in water containing carbonic acid, it should, theoretically, be capable of being assimilated by plants, but whether it is so or not has yet to be ascertained experimentally. It would seem probable, therefore, that the addition of ferrous sulphate may have a deleterious action on superphosphates, that is to say on mono- and bicalcium phosphates, especially when the iron salt is present in a very finely-divided condition.

When precipitated tricalcium phosphate is treated with ferrous sulphate, a considerable portion of the phosphoric acid is rendered soluble in ammonium citrate, so that in this case the action of the iron salt would appear to be beneficial; ferrous sulphate seems, however, to have no action on tricalcium phosphate in the form of bone-ash, mineral phosphates, &c.—F. S. K.

PATENT.

A Composition for Firing Ammoniacal Nitrogen used in Agriculture. J. T. Knowles, London. From L. Buroni and P. Marchand, Piacenza, Italy. Eng. Pat. 12,432, July 5, 1892.

It is proposed to prevent the loss of ammoniacal nitrogen from animal excreta by means of sulphuric acid, which is employed in the form of a composition termed "azotol." The composition is obtained from organic substances containing hydrogen and oxygen in the same proportion in which they are contained in water, such as dry straw, sawdust, &c. 25—50 per cent. of these are mixed with 50—75 per cent. sulphuric acid, allowed to stand until cold, and reduced to powder. The charred mass contains in this state up to 75 per cent. free sulphuric acid, and may be scattered upon dunghills or left exposed in stables.—H. A.

PATENTS.

Improvements in and connected with Pans for Boiling or heating Sugar or Compounds thereof or similar Substances. R. Morton and T. Morton. Eng. Pat. 19,762, November 14, 1891.

THE patentees claim that they effect a great saving of heat by the combination of a high and low pressure steam pan in such a manner that the exhaust steam of the high pressure pan is utilised in the low pressure pan. They likewise claim the insertion of a perforated coil between the jacket and pan, and of a non-perforated coil within the pan to expedite the boiling in the case of the high pressure pan.—A. R. L.

Improvements in Evaporating or Concentrating Saccharine Liquids and in Apparatus therefor. D. Stewart, Glasgow. Eng. Pat. 20,887, December 1, 1891.

THE patentee describes a new form of apparatus in which saccharine solutions are drawn up an exhausted feed-pipe which passes within a "main pipe" through which latter steam is introduced at its lower portion, to accomplish the

heating. The "main pipe" is curved at its upper portion and is connected by another pipe, which descends, to a condenser or receptacle, and leads the condensed vapours thereto, the whole system being exhausted by a vacuum-pump. The feed-pipe terminates within a chamber forming the top portion of the "main pipe," and the heated liquid overflows into this chamber, passing downwards through gratings in the form of a shower. These gratings lead to a series of pipes which are also in direct communication with the vacuum pump; they are placed within the "main pipe" and are packed round the feed-pipe running parallel to it. As the liquid descends, this series of pipes, the heat of the steam circulating in the "main pipe" causes rapid evaporation, which is accelerated by the diminished pressure. The vapours or gases give out their heat as they rise. The "main pipe" is preferably encased to diminish loss of heat by radiation.—A. R. L.

Improvements in Apparatus for Evaporating Saccharine or other Solutions or Liquids. P. Labric, Paris, France. Eng. Pat. 22,089, December 17, 1891.

THE patentee claims the combination with an evaporating (vacuum) apparatus of a pipe passing into the pan and terminating within it near the upper portion, for continuously supplying the liquid to be evaporated, and of a second pipe of lesser diameter placed within the first for carrying off the vapours to an exhauster. The space between the two pipes is sealed off at the upper portion, and the liquid, already heated by having passed over the exterior surface of the inner pipe at the same time as the hot vapours are passing through it, is delivered into the pan by a small descending pipe joined to outer pipe. The termination of the inner pipe within the pan is above that of the outer one, and its end is open to receive the vapours. The invention may be applied to existing apparatus.—A. R. L.

Improvements in Refining Sugar. E. Langen, Cologne, Germany. Eng. Pat. 420, January 9, 1892. (Amended.) (This Journal, 1892, 448.)

THE amendment forms no part of the invention, but relates to a more minute description of the Wulff or Bock process (*loc. cit.*).—A. R. L.

A New or Improved Process and Apparatus for the Treatment and Purification of Raw Sugar and its Conversion into Blocks or Ingots. C. M. Lafontaine, London. Eng. Pat. 15,816, September 3, 1892.

RAW sugar crystals are subjected to the action of steam in a closed centrifugal machine for about 15 minutes, to free them from molasses, so far as to allow of their being subsequently converted into a "malleable" mass by pressure. About 3 per cent. of a solution of gum tragacanth (0.5 per cent.) and syrup (5 per cent.) is now added, and the mixture rotated in the centrifugal machine for a further 3 or 4 minutes. In this state the mass is conveyed to a consolidating apparatus to be moulded by pressure. The claims refer chiefly to the invention of this apparatus, which is minutely described.—A. R. L.

Process and Apparatus for the Production of Invert Sugar and Dextrose. A. Rümpler, Tschanchelwitz, Germany. Eng. Pat. 15,897, September 5, 1892.

THIS invention relates to a process for the inversion of sugar or the saccharification of starch by means of volatile or gaseous acids in such a manner that the acids may be recovered and used over again. The plant described consists of two or more vessels or autoclaves, heated by steam coils, and capable of withstanding a pressure of 12–15 atmospheres. Sugar (100 parts) is dissolved in water (25 parts) and after introducing the syrup into one of the vessels, it is treated best with such a quantity of SO_2 that a 5 per cent. solution of the acid is obtained. The whole is now heated for about 30 minutes at 100° C. The invert sugar solution thus produced has the consistency of honey, and is ready for use. The saccharification of starch is effected by similarly heating a mixture of starch and water (equal parts) at a temperature of 120° C. for three hours. The vessels are connected together with a condensing apparatus by means of which the acid may, after the inversion is effected, be distilled from one vessel into the other.—A. R. L.

XVII.—BREWING, WINES, SPIRITS, Etc.

The Lixiviation of Apples in Cider-making. M. H. Jay. Monit. Scient. September 1892, 636–639.

THE author has analysed the liquids obtained by pressing apples and afterwards treating the pressed residue with water, pressing this and adding the filtrate to fresh-pressed apples and again pressing, treating the first pressed residue with water, again pressing it, rejecting the residue, and treating the second-pressed residue with the filtrate, pressing the residue and adding the filtrate to fresh-pressed apples, and so on.

He finds that working in this way he is practically able to exhaust the apples without obtaining the extract in an inconveniently dilute condition.

A curious fact was noted, viz., the juice of pressed apples is levo-rotatory, but the extract obtained after treating the pressed residue with water and again pressing is dextro-rotatory.—A. L. S.

The Hops of the Year 1891. M. Levy. Chem. Ztg. 16, 1892, 839–840.

Morphological Examination.—Fifty hop cones were dried at 50°–60° C. for half a day.

The cones were picked to pieces by pincers, and the leaves, perigons, seeds, and lupulin separated by sieves of appropriate mesh. This is easy to do if the cones have been properly dried. The various portions were then weighed, and the results are shown in the following table:—

Chemical Examination.—The hops were dried for 6 hours at 90—100° in a drying oven, weighed, and then dried again until they ceased to lose weight. Five grms. of hops were boiled with 250 grms. of water for $\frac{1}{2}$ of an hour; the hops were filtered off and dried and the aqueous extract calculated from the loss in weight. Five grms. of hops were extracted for 2 hours in a Soxhlet apparatus with 91 per cent. alcohol. The alcoholic extract is calculated from the loss of weight of the hops, and also from the weight of the extract obtained on drying at 60—70° for 3 hours. In this way some hops yield fine yellow crystals. The ethereal extract was obtained in the same way. The ether used was dried over sodium.

The hop oil was determined by boiling 10 grms. of hops in a reflux condenser with 150 cc. of water. The whole is then extracted with ether, the ethereal solution separated, the ether evaporated, the residue dried at 50°–60° C., and weighed. The colour communicated to the worts by boiling with the specified hops was determined by boiling 1 gm. of hops with 300 grms. of water for $\frac{1}{2}$ hour; 160 cc. of this solution were placed in a cylinder and distilled water in another cylinder was brought to the same colour by adding $\frac{N}{100}$ to the solution.

The following results were obtained:—

As the amount of moisture present in hops varies greatly, it is important that the results be expressed in terms of the dry substance.

It is evident that the percentage of alcoholic extract is the important factor in the chemical examination of hops; in the best hops this lies between 24 and 29 per cent., in

medium quality hops, between 20–24 per cent., and in poor hops, below 20 per cent.

The samples of Auer, Hollbauer, and Roth-Auschauer were badly dried, whilst the sample of Wohnzacher appears to have suffered from rain.

—A. L. S.

On the Formation of Dextrase from Starch by Ferments.
C. J. Lintner. Zeits. ges. Brauw. 1892, 15, 123.

WHILST Cuisinier (this Journal, 1887, 829) found a ferment (glycase) in barley, which converts starch into dextrose, yet the author (this Journal, 1889, 560) has previously denied the existence of this, since although he found maltose, he found no dextrose.

Further experiments have shown Lintner that he is wrong. Barley and wheat contain a little glycase, but maize contains it in quantity.

To prepare dextrose, a boiled or unboiled starch conversion is made into a thin paste with coarsely-ground maize and kept at 60° C. for 30–48 hours; the optical activity will then have sunk to $[\alpha]_D = 53^\circ$ and the filtrate when concentrated will crystallise.

Glycase, although it only exists in an insoluble condition in maize, exists in a soluble condition in malt. Amongst the conversion-products of starch, dextrose can be recognised, although the amount is but small when compared with the amount of maltose.—A. L. S.

On the Preparation of Iso-Maltose from Starch Transformation Products obtained by Diastase. C. J. Lintner and G. Dill. Zeits. ges. Brauw. 1892, 15, 145.

ONE of the authors has previously (Zeits. ges. Brauw. 1892, 15, 6; this Journal, 1892, 627) given a general method for the preparation of iso-maltose; he now gives a detailed account of its preparation as follows:—250 grms. of potato starch are mixed with 500 cc. of diastase solution at 55° C., containing 0.5 gm. of diastase (this Journal, 1887, 296), and 2 litres of water at 75° C. After complete solution, another 0.5 gm. of diastase is added and the reaction allowed to proceed for three hours at 65°–69° C.

The iodine reaction is reddish-brown, $[\alpha]_D = 170^\circ$ approximately.

The solution is evaporated to a syrup, saturated with 80 per cent. alcohol and poured into hot alcohol. Sufficient alcohol must be used, so that every 100 parts of 80 per cent. alcohol do not contain more than 10 parts of dry substance. After cooling, the clear solution is decanted and the alcohol distilled off. The residue is diluted to a

20 per cent. solution and yeast added—in order to destroy the maltose and dextrose. This is found to have taken place in about 20 hours. The fermented solution is filtered, decolorised with animal charcoal, evaporated to a syrup and precipitated with 85 per cent. alcohol; there must be 100 cc. of 85 per cent. alcohol for every 5 grms. of dry substance. The solution is evaporated and the syrup treated in the same way but with 90 per cent. alcohol, so that 100 cc. of alcohol are present for every 3 grms. dry substance. The clear alcoholic solution contains iso-maltose with at the most but a trace of dextrose. This may be removed by fractionation with alcohol. To obtain the iso-maltose in a solid condition it is preferable to mix the syrup with powdered glass and dry at 100° C. In this way 20 per cent. of the starch are obtained as iso-maltose.

The Hydrolytic Functions of Yeast. (Part II.) James O'Sullivan. Proc. Chem. Soc. 1892, 147. (This Journal, 1892, 628.)

A FURTHER series of experiments on the hydrolytic activity of healthy yeast cells are described, the following being a summary of the conclusions arrived at:—

1. The hydrolytic action of yeast at ordinary temperatures (12° to 20° C.) follows the same course as that of a simple

chemical interchange, and is not influenced by either air or carbon dioxide.

2. A time curve representing the action would correspond with that given for invertase under the most suitable conditions of acidity by O'Sullivan and Thompson (this Journal, 1890, 816 and 1049). The rate, therefore, differs from that at which the alcoholic fermentation of yeast takes place, which would be represented by a straight line (Dumas, Ann. Chem. Phys. [3], 1874, 81; and A. J. Brown, this Journal, 1892, 257).

3. Any interference involving either an increase or a diminution of the natural acidity of the yeast cell diminishes its action. This is a very important matter, and should always be considered when dealing with organisms or cellular membranes possessing the power of hydrolysing cane sugar. Dumas observed that both acids and alkalis interfered with alcoholic fermentation, and that in the case of alkalis the yeast possessed the power of overcoming the alkalinity, the liquid again becoming acid and fermentation recommencing. It is found that a quantity of potassium hydrate which completely arrested the hydrolytic action of yeast for three to six hours was neutralised by the yeast in about 24 hours, the solutions eventually becoming acid and hydrolysis recommencing.

4. It is inferred from experiments on the effect of rupturing the cell on the velocity of the hydrolytic action, and also from the rate at which the change proceeds, that the whole of the invertase of the yeast cell comes into action as soon as the cane sugar is added to the yeast, and that it continues to act during the progress of the hydrolytic action.

5. The power which yeast possesses of producing alcoholic fermentation is not influenced by the yeast having first hydrolysed cane sugar, this being the case whether the hydrolytic action is brought about in the first instance in the presence of air or carbon dioxide.

PATENTS.

Improvements in the Production of Alcoholic Ferments and of Fermented Liquids thereby. J. Takamine, Chicago, U.S.A. Eng. Pat. 17,374, October 12, 1891.

THE basis of the invention is the convenient use of a mould which the inventor proposes to call *Aspergillus Koji*, which has the power of secreting a diastatic ferment and also of producing the alcoholic fermentation of sugar. There are other moulds which likewise possess these properties. *Aspergillus Koji* is well known in Japan and is called Moya-shi or Tane-Koji. To prepare this in quantity, any suitable cereal is ground and steamed, until the starch cells are burst, cooled to 26°–30° C., and a small quantity of the mould spores well mixed with it.

When the mould has fully matured, the product may be used, or if it is required to preserve it, the spores are sifted out, dried and mixed with gypsum or roasted starch, when they will keep for a long period.

To produce the diastase, any convenient cereal is ground, steamed, and cooled to 30° C. The mould is mixed with this and allowed to grow on it. When sufficient growth has taken place, the mass is extracted with water. The liquid contains the ferment cells in suspension and the diastase in solution; they are separated by filtration.

The cereals to be converted are heated with water until the starch is thoroughly gelatinised and then cooled to 60°–75° C.; the solution containing the diastase is added and in about one hour complete conversion has taken place.

When cold the ferment cells, which were previously filtered out, are added, and the usual alcoholic fermentation takes place. This ferment will grow in solutions containing considerable quantities of alcohol, so that it is possible to obtain a fermented liquid containing about three times as much alcohol as usual.—A. L. S.

Improvements in the Manufacture of Beer and Porter or like Beverages. J. Hillyard, Liverpool, and E. Dugdale, Liverpool. Eng. Pat. 17,395, October 13, 1891.

MALT with or without other flavouring matter, is mashed at a high temperature and after standing two hours is boiled with hops until the malt "breaks." The boiling liquor is then run into casks and the casks shived. When the liquid has become fine it is ready for consumption and forms a non-intoxicant beer.—A. L. S.

An Improved Process for Filtering Beer and other Liquids, and Apparatus therefor. J. Sutton, Islip, New York, U.S.A. Eng. Pat. 18,488, October 27, 1891.

BETWEEN the vat and the filter is placed a tall stand-pipe up which the liquid may be forced by pressure; this pipe is bent over at the top and continues downwards to the filter, the liquid is only forced part way up the stand-pipe by pressure, it being drawn over the bend by the siphoning action of the descending pipe. By this means the inventor claims that the liquid is freed from much of its sediment and heavy matter before entering the filter. Several methods and apparatus for employing this system are described in detail in the specification.—J. C. C.

Improvements in Pneumatic Malting and in Machinery or Apparatus therefor. R. H. Leaker, Bristol. Eng. Pat. 18,538, October 28, 1891.

AN attenuating coil is placed in the vessel which contains the drum usually employed in pneumatic malting. By means of this the temperature of the grain in the drum may be regulated as required. Over the drum is fixed a trough, containing an attenuator, and the edges of a fibrous blanket dip into the water in this. The air supplied to the drum has to pass through this blanket, and thus may be supplied to the grain with any degree of moisture or heat required.—A. L. S.

Improvements Relating to the Manufacture of Beer. P. A. Roche, Paris. Eng. Pat. 19,849, November 16, 1891.

THE invention has for its objects the rendering of beer ferruginous. This is done by passing an electric current through beer, into which iron in the form of thin wire has been introduced.—A. L. S.

Improved Process for the Production of Yeast and Spirit by the Employment of Ozonised Air or Oxygen. W. P. Thompson, Liverpool. From O. E. Nycander and G. Francke, Hamburg and Berlin, Germany. Eng. Pat. 20,566, November 26, 1891.

By the employment of ozonised air the use of crude materials is rendered possible for the production of German yeast and a commercial spirit.

Such materials are molasses, bran, malt-combs, linseed cake, animal refuse, &c.—A. L. S.

A Method of and Appliances for the Collection, Purification, and Utilisation of the Carbonic Acid Gas given off during Fermentation of Saccharine and other Substances. J. Pullman and H. S. Elworthy, London. Eng. Pat. 22,248, December 19, 1891.

IN applying this process to an open fermenting vessel, the latter must be provided with a wooden or metallic cover, having a deep flange or rim which fits into a corresponding deep gutter fixed round the outside of the vat and a little below the top. This channel is partially filled with some liquid, such as water, mercury, &c., which prevents the escape of gas or the entrance of air. One cover may thus serve for several vats, being transferred from one to the

other by means of an overhead railway and a system of pulleys and ropes. In the case of large fermenting vessels the cover may be formed of waterproof or oiled canvas, suitably secured at the edges. The gas escapes from the vat through a valve, which is set to open at a certain pressure (2–3 inches of water), and is then preferably collected in a gasometer. Subsequently the gas is submitted to the following purifying processes. It is passed through—

1. A cylindrical scrubber containing coke, pumice, &c., over which a slow stream of water is made to flow by means of an automatic sprinkler. Soluble impurities, such as alcohol, acetic ether, &c., are thus removed from the gas.

2. A similar scrubber, in which the gas encounters, instead of water, a current of melted paraffin wax, or vaseline, &c., which absorbs the ethereal impurities.

3. A desiccating chamber charged, preferably, with potassium carbonate or calcium chloride.

4. A series of pipes maintained at a red heat. The first of these pipes contains coke, metallic copper, iron, or zinc, and is intended to retain any free oxygen present in the gas. The remaining pipes are charged with copper oxide or some other suitable oxidising material, and serve to oxidise any organic impurities still present. By these means the carbonic acid gas is rendered perfectly pure, and after cooling, may be compressed or liquefied in the usual way.

—H. T. P.

Improvements in or in the Preparation of Extracts for use in the Manufacture of Yeast and Spirits. W. Thompson, Liverpool. From O. E. Nyeander, Berlin, Germany. Eng. Pat. 22,399, December 22, 1891.

THE object of this invention is the production of a yeast-food suitable more particularly for use in distilleries and yeast manufactories, from various nitrogenous materials hitherto not employed for this purpose, such as raw and dried slaughter-house and fish refuse, oil-cake and meal, &c. The nitrogenous bodies are rendered assimilable (peptonised) by heating the material employed under pressure, with or without the addition of organic or inorganic acids. Or peptonisation may be effected at 30°–50° C. by treatment with pepsin, malt, malt-extract, lactic acid, &c. The extract thus obtained is added to worts, saccharine solutions, &c., which are then fermented in the usual way.—H. T. P.

Improvements in Apparatus for Cooling and Attenuating Beer during Fermentation. H. Prior, Linton, Cambs. Eng. Pat. 301, January 6, 1892.

THE apparatus consists of a shallow, closed, circular vessel, in the interior of which are placed one or more cooling coils. The ends of the coils extend through the shell of the vessel, the inlet end being provided with a tap for regulating the flow of water. The tray, being filled with water, is lowered into the vat, level with the surface of the beer, and cold water is circulated through the coils. The water in the tray is cooled to an even temperature, and a large and uniform cooling surface is thus exposed to the beer. It is claimed that by this means a more uniform distribution of temperature is obtained and greater control over the beer, as well as a larger development of yeast than hitherto possible.—H. T. P.

Improvements in Apparatus for Drying Brewers' Grains and similar Substances. H. H. Lake, London. From E. M. Parker, New York, U.S.A. Eng. Pat. 15,559, August 30, 1892.

THE apparatus consists of a cylinder made of three curved plates which do not quite meet, and leave a longitudinal opening for the escape of steam, &c. Through the axis of the cylinder passes a hollow screw for conveying the grains and furnished with longitudinal paddles to prevent the grains lying at the bottom of the cylinder. The walls of the

screw cylinder are pierced, and hot air being injected into the screw passes through the perforations into the grains and thence through the opening in the top of the cylinder.

—A. L. S.

Improvements in Malt Beverages. E. Adam, Philadelphia, U.S.A. Eng. Pat. 17,258, September 27, 1892.

BOILED, hopped, and cooled wort prepared in the ordinary way from high-dried malt or other suitable material, is stored in an air-tight vessel in which it is fined and allowed to deposit its suspended matters. The wort is then mixed in a suitable apparatus with some fermented or distilled liquid, such as alcohol, wine, cordial, &c., and at the same time charged with carbonic acid gas. Finally, the liquid is filtered under pressure and stored for consumption.

—H. T. P.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

(A.)—CHEMISTRY OF FOODS.

Is Milk Acid or Alkaline? A. Vaudin. Bull. Soc. Chim. 7—8, 1892, 483—492.

THE author has examined the milk of various animals, and gives the following summary of his investigations:—

1. The milk of mammals has an acid reaction at the moment of its escape from the mamme.

2. The acidity of normal milk, furnished by animals of the same species, undergoes relatively little variation.

3. All influences (gestation, parturition, food, &c.) which can cause disturbance of the lactic secretion bring about a change in acidity.

4. The acid reaction of milk is due principally to the proteid constituents which it contains.

5. The variations in the acidity, which take place in the course of lactation, depend on the modifications, both in nature and in proportion, which the various proteids and mineral constituents of the milk undergo at the same time.

A New Colour Standard for Natural Waters. A. Hazen. Amer. Chem. Jour. 14, 300.

See under XXIII., page 1037.

PATENTS.

Improvements in the Preparation of Mineral Salts for Bathing and Drinking Purposes. C. W. Vincent, Holloway. Eng. Pat. 18,700, October 29, 1891.

OBJECT of this invention is to "imitate, at pleasure, the various celebrated sodio calcarco, magnesio, sulphuretted, aerated, ferruginous and other waters of France (including Savoy), and Germany, Bohemia, Austria, &c." To this end various proportions of sodium sulphate, coal, and calcium (magnesium or iron) carbonate are roasted together. The product containing chiefly the sulphate, carbonate, and sulphide of soda, and calcium sulphide, is ground up and used in the proportion of 1 oz. to 15 gallons of water. If desired, it may be exposed on shelves to the action of carbonic acid gas, until sufficiently bicarbonated.—H. A.

Improvements in Detection of Foreign Fats in Butter. W. Johnstone, London. Eng. Pat. 20,956, December 1, 1891.

See under XXIII., page 1039.

Improvements in the Smoking or Curing of Fish, Meats, and other Articles of Food. B. Piffard, Hemel Hempstead, Herts. Eng. Pat. 21,305, December 5, 1891.

THE inventor prepares an antiseptic liquid by burning wood in a suitable furnace and conducting the smoke into a tube or chimney through which steam is propelled from a boiler. The vapours are then condensed in a suitable apparatus.

The woods employed vary according to the nature of the food and the flavour it is desired to impart. The patentee uses oak for pork, peat for fish, birch for tongues, and so on.

The length of time which the food is immersed in the liquor varies according to the nature of the article and the strength of the antiseptic. When the liquor is of a dark straw colour, the time is from three to six days for pork, a few hours for fish, and one minute for imported preserved meat.—L. de K.

Process for Preserving Organic Substances and for Disinfection. O. Imray, London. From "the Farbwerke Meister, Lucius, and Brüning, Hoechst-on-the-Main, Germany." Eng. Pat. 21,706, December 11, 1891.

THE inventors have noticed that formaldehyde possesses remarkable antiseptic properties, and that putrefaction bacteria, ferment germs, mildew fungus, and the like, are completely impeded in their development by the said substance.

Meat and similar substances are immersed for a few seconds in an aqueous solution of formaldehyde: liquids are mixed with $\frac{1}{250000}$ part of it. Solid substances may also be exposed to the formaldehyde vapour. Considering the minute quantity employed, there seems not the slightest objection to its use: moreover, meat, vegetables, and similar articles of food, when treated with it, do not lose anything of their appearance or freshness, or suffer in any other respects.—L. de K.

Improvements in Gelatinous Food Products. G. Parker, Birmingham. Eng. Pat. 14,349, August 9, 1892.

THE object of the invention is to provide a gelatinous product or mass in which a portion, or all, of the flavouring material required for the mass will be contained, without being mixed with the gelatin, and which will require only water or milk to prepare it for use.

The flavouring ingredients are placed in a cavity inside the jelly. As regards the composition of the mass, or its final shape, the inventor does not limit himself to any particular description, but a desirable formula is: glucose, 1 lb.; sugar, 5 lb.; gelatin, $1\frac{1}{2}$ lb.; citric acid, 1 oz. In preparing it, the gelatin is dissolved in a suitable quantity of water, the glucose and sugar boiled, the citric acid added, and the whole mixed so as to form a solid mass, body, or compound.—L. de K.

Improved Process for Preserving Meat and other Articles of Food. G. Hartmann, Frankfurt a M., Germany. Eng. Pat. 14,601, August 12, 1892.

THIS process dispenses with the use of antiseptics, and consists in three steps: preliminary sterilisation, germinating period, and final sterilisation. The first step consists in subjecting the preserves to a temperature of 100° – 120° for a short time; the second, to keep them for some days at a temperature of 20° – 30° .

This will develop any germs or bacteria which have not been destroyed in the primary sterilising process, but they are too weakly and too poor to rapidly multiply and form colonies, and if no time is given them to properly develop, they will be utterly destroyed by a second sterilisation process (3rd step).

Preserves of almost unlimited durability are thus obtained.—L. de K.

A Process for the Disacerbation of Kola-Nut Powder. H. Hoffmann, Berlin, Germany. Eng. Pat. 16,765, September 20, 1892.

THE invention has for its object the removal of the bitter taste of kola nuts so as to render them fit for food. Hitherto the disacerbation has been usually effected by treatment with alkalis, but now hydrogen peroxide is proposed.

The powder obtained from the slightly-roasted kola nuts is moistened with water and mixed with "10 per cent. (ten-hundredth parts) of peroxide of hydrogen." The reaction is somewhat energetic, and the temperature rises to 35° . After a few hours the reaction is completed, and the bitter principles, chiefly tannins, are oxidised and destroyed. The resultant pulp is then dried at a slow heat and is ready for use.—L. de K.

(B.)—SANITARY CHEMISTRY.

Microscopic Examination of various Forms of Carbon; Identity of Lung-Pigment with Soot. J. Wiesner. Monatsh. 13, 1892, 371–410.

THE author has examined microscopically the behaviour of various forms of carbon on treatment with potassium bichromate and sulphuric acid at the ordinary temperature; the following is a summary of his observations:—

The principal constituent of lignite is a brown transparent substance, which becomes colourless when treated with a mixture of sulphuric acid and potassium bichromate, being converted into a web-like skeleton of an indefinite histological character, and which shows the reactions of cellulose; as this residue does not withstand the action of chromic acid, the lignite, excluding mineral constituents, is finally completely oxidised.

All the other kinds of carbon which were investigated, namely, anthracite, coal, charcoals, soot, and graphite, contain as a rule only a small quantity of substances which are readily oxidised by the chromic acid mixture: the residue behaves like amorphous carbon, and is only extremely slowly acted on by chromic acid at the ordinary temperature.

Anthracite consists for the most part of a black substance which is practically unacted on by the chromic acid mixture: it also contains a dark brown transparent substance, which is slowly oxidised, but which does not yield cellulose.

Coal behaves like a mixture of lignite and anthracite, and on treatment with chromic acid gives a small quantity of cellulose.

Red charcoals, obtained by carbonising wood at a relatively low temperature, is completely decomposed by sulphuric acid and potassium bichromate; at a certain stage in the decomposition process there is formed a well-preserved woody skeleton, in which are seen long dark threads and delicate rings; by this behaviour it can be distinguished from lignite. Black charcoal is hardly acted on by the chromic acid mixture.

Soot, freshly deposited from a flame, consists partly of exceedingly small black particles of carbon, which are not oxidised by the chromic acid mixture, and partly of oily drops. Soot deposited from the air consists partly of fine particles, partly of dendritic or irregular aggregates, of carbon.

The black pigment which collects in the human lung, especially in the interlobular connective tissue, consists of smaller or larger particles of soot, which, on treatment with chromic acid, are simply resolved into small granules without any further action taking place. Melanines can be readily distinguished from the particles of lung-pigment as they are rapidly destroyed by the chromic acid mixture.

Chemically pure, amorphous carbon, prepared from soot, and containing 99.3 per cent. of carbon, behaves towards chromic acid like the other substances consisting of amorphous carbon, which have been mentioned; it is, however, much more readily oxidised, probably owing to its fine state of division.—F. S. K.

PATENT.

Improved Apparatus for the Purification of Gaseous Fumes, Air, and the Like, and the Deposition of Solid Particles therefrom. M. F. Purcell, Dublin, and G. Purcell, Los Angeles, California. Eng. Pat. 21,730, December 11, 1891.

THE apparatus described in this patent may be employed for the purification of smoke or of other waste gases containing solid particles, as, for example, the air containing dust from screened grain; also for the purification of deleterious gases from various manufactures.

It consists of an ordinary exhaust fan, into the casing of which a number of nozzles are introduced; water mixed with suitable chemicals or not, as the case may be, is caused to impinge on the vanes of the rotating fan, and in this way is immediately broken up into a fine mist in contact with the gaseous fumes. This method of treating the fumes not only cools them and reduces their volume, but removes all solid matter; in case ammonia or any other readily-soluble gas is present in the mixture it is dissolved, and the escaping gases are transparent and innocuous.—F. S. K.

(C).—DISINFECTANTS.

Formaldehyde ("Formol"). M. Trillat. Monit. Scient. July 1892, 490—494.

HITHERTO it has been thought that the most powerful antiseptic bodies belonged to the hydroxyl compounds of the aromatic series of hydrocarbons and to the metallic salts. Formaldehyde is, however, a very powerful antiseptic, the author finding it to be superior to bichloride of mercury in this respect. This result is unexpected, as acetaldehyde does not possess this property.

It had been previously noticed in 1888 that the presence of a minute quantity of this substance in urine effectually preserved it from putrefying. Similar results having been obtained with other bodies, the author was led to the further study of this aldehyde, with special reference to its probable use in the preservation of fermentable products.

Preparation and Manufacture of Formaldehyde.—Fischer and Löw prepare small quantities of formaldehyde by allowing the vapours of methyl alcohol to come into contact with a spiral of platinum, previously heated. The platinum remains incandescent, whilst in its vicinity the alcohol is oxidised to aldehyde.

The industrial apparatus is constructed to work out the following principle:—A conical jet discharges the alcoholic vapour from a narrow opening. The proportion of air mixed with alcohol increases in proportion as the base of the cone is enlarged, i.e., in proportion as the distance increases from the apex of the cone. In the different parts of the jet a zone is found in which the mixture of air and alcohol is in the most favourable condition for oxidation, which is stimulated by the presence of a red-hot porous surface. It is easy to understand that the portions of the alcoholic jet near to the summit of the cone, and which only contain little oxygen, will only undergo imperfect oxidation, whilst those very far away, but very rich in oxygen, will be almost completely burned. But between the two extremes is the portion best adapted for the oxidation, the process being regulated by estimating the distance which should separate the orifice of the jet from the red-hot porous body.

Methyl alcohol, heated under pressure, escapes from a horizontal jet which operated in a copper tube, the opening of which is conical, so as to allow of the in-draught of air. After the passage over the oxidising substance the vapours are at once condensed by various processes. Thus a mixture of water, methylic alcohol, and formic aldehyde is obtained, and also traces of formic and acetic acids. A rational process of purification is next proceeded to. Löw, Fischer, and Tollens propose as oxidising agents platinum, platinised asbestos, and oxide of copper. The author also finds many metals and most porous bodies, as coke, retort-carbon, porcelain, &c., similarly efficacious.

Mention is made of the formation of trioxymethane when a solution is evaporated to a greater strength than 36° — 40° C. In noticing its action on wines the author proposes to found a method of analysis on the results obtained; the tannin and colouring matters being precipitated by the aldehyde.

It is found that the addition of 1—50,000 of meat extract has a decided preservative action, while with 1—25,000 no change could be noticed in the extract after the lapse of four days. Bichloride of mercury in these proportions has no effect, the extract showing change in 24 hours. With 1—12,000 the extract is kept good for several weeks, while change takes place in five days when using equal weight of bichloride of mercury.

Several kinds of bacilli are destroyed by a solution of 1—25,000, among which may be mentioned that of the saliva, &c.

Preservation of Meat.—Three methods are described: (1) by immersion in the aldehyde solution; (2) by means of the vapour of the aldehyde; (3) by wrapping the meat or other perishable goods in coverings soaked in aldehyde solution.

The following results were obtained by (1):—

Strength of Solution 1—500.

Time of Immersion.	Time of Preservation.
60 minutes.	25 days.
40 "	18 "
30 "	16 "
15 "	13 "
10 "	12 "
5 "	8 "

and

Strength of Solution 1—250.

Time of Immersion.	Time of Preservation.
5 minutes.	20 days.
2 "	16 "
1 "	12 "
30 seconds.	10 "
2 "	10 "

The above experiments were performed on ribs of beef, which were allowed to remain exposed to the air, at a temperature of 23° — 30° C.

The vapour of aldehyde was found to stop all decomposition, keeping meat fresh for months and stopping fermentation in organic liquids.

Pieces of veal were wrapped in coverings soaked in 1—250 solution with success.

Analyses of the meat juices and microscopical examination of meat tissues showed that no alteration had taken place from the action of the aldehyde.—W. P. D.

XIX.—PAPER, PASTEBOARD, Etc.

PATENTS.

Improvements in and relating to the Manufacture or Production of Paper Pulp and Textile Fibre. C. G. Hagemann, Ludwigshafen, Germany. Eng. Pat. 18,470, October 27, 1891.

It is found that the rush *Arundo Donax* is sufficiently purified by a relatively weak solution of caustic alkali at the ordinary temperature for utilisation as a cellular substance or paper pulp. Thus this particular vegetable fibre is not weakened and turned brown by the alkali, as are other fibres, which can only be purified by such strong solutions of alkali and at such high temperatures as have the deleterious effects indicated. The *Arundo Donax* is comminuted and immersed in a solution of caustic soda of 4—6° B., for 4—6 days; the fibrous mass is then washed, crushed by rolls, edge-runners, or stampers, ground with water, but without chemicals, in a rag-engine, and finally bleached, washed, and dried in the known manner. To produce a textile fibre the rush is split into long strips by light rolling: the strips are treated with alkali as described above, washed, and beaten with wooden beaters upon wooden supports; carding, heating, or thrashing, as applied to hemp, complete its conversion into a fibre which can be spun. To obtain a very soft fibre the beaten strips are allowed to rot in water in the same manner as is carried out in the case of hemp, flax, &c., the finishing processes being the same as those described above. The waste from the conversion into textile fibres may be made into paper-pulp as detailed.—A. G. B.

Improvements in the Method of and Apparatus for making Parchmentised Fibre Tubes. R. P. Frist and C. G. Ruper, Newcastle, Delaware, U.S.A. Eng. Pat. 22,628, December 28, 1891.

HERETOFORE parchmentised paper tubes have been made by winding the paper strips, which have been immersed in the parchmentising liquid, on a mandrel. The ease with which the wet paper is torn renders this process a difficult one. By this invention the dry strips are wound on the mandrel and subsequently parchmentised by being passed, on the same mandrel, through a bath of the parchmentising liquid; the moist paper is then consolidated by passage between pressure rollers. Thicker tubes are made by winding fresh paper over the first layer as soon as this has passed through the bath and then passing both layers through a second bath before consolidating. There are also claims for other methods for applying the liquid, such as contact with a roller surmounted by a drip-pan, and for various combinations of apparatus.—A. G. B.

Improvements in Pulp-Catchers or Savers. A. J. E. Füllner, Warmbrunn, Prussia. Eng. Pat. 13,893, July 30, 1892.

THE pulp-catcher described consists in an inverted truncated conical vessel having an annular channel above its upper edge, from which the water containing the pulp is caused to flow down the sides of the cone by means of an inner conical ring. In doing so the water deposits the pulp, the clear liquid rising up the centre and is drawn off by a second annular channel, a sieve being, if necessary, interposed to catch any remaining pulp. The pulp deposited is drawn off by a pipe which enters about half way down and terminates at the bottom near the centre of the vessel. The outer portion of this pipe may be raised or lowered in order to regulate the rate of discharge.—J. C. C.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

Transformation of Gallic Acid into Pyrogallol; Melting Point of Pyrogallol. P. Cazeneuve. Bull. Soc. Chim. 7—8, 1892, 549—551.

WHEN gallic acid is heated with twice its weight of aniline, carbonic anhydride begins to be evolved at about 120°, and the whole of the gallic acid can be decomposed without raising the temperature much above this point. If the heating be continued until the evolution of gas is at an end crystals of aniline pyrogallate $C_6H_5O_3 \cdot 2 C_6H_5 \cdot NH_2$ are obtained on cooling; this compound is very unstable and melts at 55°—56°; when treated with benzene or toluene it is decomposed, aniline passes into solution, and pyrogallol remains in a practically pure condition.

Pure pyrogallol melts at 132°, not at 115° as generally stated.—F. S. K.

On some Ferruginous Medicinal Preparations. H. Le Chatelier. Compt. rend. 115, 1892, 124—125.

THE author finds that many mineral ferruginous waters, as they occur in commerce at the present time, contain little if any iron. Also that many pharmaceutical preparations of iron are of very uncertain composition, both as regards the presence of iron and the condition of oxidation in which it is present.—A. L. S.

Investigations on Coca Leaves. O. Hesse. Annalen, 271, 1892, 180—228.

FIVE kinds of coca leaves are to be distinguished, viz.:—(1) Broad-leaved coca from Peru and Bolivia (*Erythroxylon coca*, Lamarek); (2) small-leaved coca from Northern Peru, and exported from Trujillo, hence known as "Trujillo," or "Truxillo coca" (*Erythroxylon coca*, var. *novagranatense*, Morris); (3) a coca from South America; formerly sent to Paris, and which stands between the above two varieties in its physical character. This variety has not been an article of commerce for the last five or six years. (4.) Broad-leaved coca from British India and Ceylon (*Erythroxylon Bolivianum*, Burck), only occurring to a small extent in commerce: (5) small-leaved coca from Java (*Erythroxylon coca*, var. *spruceanum*, Burck.); 20,000 kilos. of this variety were imported last summer. The last two varieties have been cultivated from seeds, and it is uncertain whether they are indigenous or not.

The Coca Alkaloids (this Journal, 1889, 566):—

1. *Cocaine*.—Reference is made to Einhorn's work on this alkaloid in regard to the decomposition of the alkaloid into benzoyl ecgonine and methyl alcohol by means of water (this Journal, 1886, 40; 1887, 605). This decomposition appears to take place in coca itself when it is not quite dry, and when damaged by water, the leaves were found to contain considerably less cocaine than fresh coca. Ecgonine itself, when heated to 140°—160° C. with 25 per cent. sulphuric acid, is converted into anhydro-ecgonine, the hydrochloride of which, $C_{14}H_{17}NO_2 \cdot HCl + HO_2$, melts at 238°—240° C. when dehydrated.

2. *Iso-cocaine*.—This dextro-rotatory cocaine does not occur in coca, and Liebermann's statement to the contrary is incorrect. It has only been obtained synthetically.

3. *Cinnamyl-cocaine*.—This alkaloid is seldom found in the broad-leaved coca from South America, and then only in small quantity, but always occurs, and often in considerable quantity, in the small-leaved Truxillo coca; it is an especially prominent constituent of the East Indian coças. Java coca, yielding 1.9—2.1 per cent. of alkaloids, was found to contain about 1 per cent. of cinnamyl-cocaine.

In order to isolate it from the mixture of alkaloids obtained from Java coca, the whole is precipitated from acid solution with a small excess of ammonia and the resinous precipitate covered with alcohol or ether in the cold, when crystals of cinnamyl-cocaine separate, which can be re-crystallised from hot alcohol. They dissolve with difficulty in alcohol, ether, acetone, and petroleum ether, and melt at 121°C . Of the salts of the alkaloid, the hydrochloride and the platinum and gold double chlorides are characteristic; it also forms a methiodide, $\text{C}_{19}\text{H}_{21}\text{NO}_4 \cdot \text{CH}_3\text{I}$. Cinnamyl-cocaine was first obtained synthetically by Liebermann.

4. *Cocamine* was obtained by the author in 1886 from the South American variety formerly sent to Paris, and was found to form about one-half of the total alkaloids present. To separate it, the mixture, dissolved in acetic acid, was treated at 50°C . with ammonium and petroleum ether, and this treatment repeated with the precipitate obtained, until it was finally obtained in a micro-crystalline, flocculent form. When heated the alkaloid is decomposed, but the decomposition is effected better by means of dilute acids, when ecgonyl-cocaine acid, $\text{C}_{27}\text{H}_{39}\text{NO}_5$, results as the first product of decomposition, which is itself readily decomposed further into eegonine and cocaine acid. This last acid is best purified by converting it into the ammonium salt; it melts at $266^{\circ}-267^{\circ}\text{C}$., and is regarded as a polymeride of cinnamic acid. The molecular weight of cocaine as determined by Raoult's method corresponds to the formula $\text{C}_{14}\text{H}_{23}\text{NO}_4 \cdot \frac{1}{2}\text{H}_2\text{O}$.

5. *Iso-cocamine* occurs in all varieties of coca, but especially in Truxillo coca, and is contained in the mixture of bases which is precipitated from the acid solution that results after the removal of cocaine and cinnamyl-cocaine by means of ammonia or of sodium carbonate. It could not be isolated successfully owing to lack of material, but its properties are known owing to its having been synthesised by Liebermann under the name of β -truxillin. It is isomeric with cocaine and closely resembles the latter in all properties and reactions, being decomposed by acids with the formation of ecgonyl-iso-cocaine acid and iso-cocaine acid successively. The iso-base is somewhat more soluble in petroleum ether than cocaine. Cocaine and iso-cocaine acids can be readily distinguished by the action of barium or calcium chloride on their ammoniacal solutions, when the salt of the latter is precipitated, that of the cocaine acid remaining in solution. The iso-cocaine acid can then be isolated from the precipitate by decomposing it with hydrochloric acid and extracting with ether.

6. *Homo-cocamine* occurs in small quantity in Truxillo coca and in the broad-leaved South American coca, judging from the formation of homo-cocaine acid as a decomposition product of the mixed alkaloids by means of acids. The properties of this acid and its method of separation from cocaine and iso-cocaine acid are detailed. It has the same empirical formula as cocaine and iso-cocaine acids, $\text{C}_{19}\text{H}_{21}\text{O}_4$, which formula also represents its molecular weight, whilst that of the two other acids corresponds to $\text{C}_{17}\text{H}_{19}\text{O}_4$. The salts of homo-cocaine acid are all amorphous; a methyl-ester and a mononitro-derivative are described.

7. *Homo-isococamine* only exists to a very small extent in coca, and was detected by the formation of homo-iso-cocaine acid as a decomposition product. The properties and method of isolation of this acid are given. It is isomeric with homo-cocaine acid.

β -cocaine acid, $\text{C}_{15}\text{H}_{16}\text{O}_5$, is formed by fusing cocaine acid with caustic potash at a high temperature. It is isomeric with cocaine acid, and crystallises in needles from alcohol or from hot water, which melt at 180°C . The acid is hardly attacked by potassium permanganate; of its salts the copper and silver salts are amorphous precipitates, the potassium salt is crystalline and readily soluble. A methyl-ester and a mono-nitro-derivative are described. β -iso-cocaine acid is obtained in a corresponding way from iso-cocaine acid; it is identical with Liebermann's δ -truxillie acid. It melts at 172°C ., and is best crystallised from dilute acetic acid. The barium salt is crystalline and soluble with difficulty. The molecular formula is $\text{C}_{15}\text{H}_{16}\text{O}_5$; the acid yields a mono-nitro-compound.

8. *Benzoyl-pseudo-tropeine* is contained in Java coca, and is separated from the other alkaloids by precipitating the latter from acid solution by a slight excess of ammonia, when the benzoyl-pseudo-tropeine remains in solution and can be separated by the addition of caustic soda. After extraction with ether the base is converted into the hydrochloride, which can be purified by recrystallisation from alcohol. Its properties as described by Liebermann are confirmed except in regard to the nature of the base formed by decomposition with hydrochloric acid, which the author does not consider identical with Ladenburg's *Pseudo-tropeine*. In opposition to Geisel's results the author was unable to detect the presence of *Hygrine* in any of the varieties of coca (*Pharm. Zeit.* 36, 419).

Indifferent Constituents of Coca Leaves.—A red colouring matter, probably *Carotin*, was isolated six years ago from a sample of Bolivian coca, but owing to the ease with which it undergoes decomposition no analysis of the product could be made, and the author has been unable to isolate it since from any of the varieties he has examined. The presence of *Coca wax* was first pointed out by Niemann, and was regarded as probably identical with "*Grass wax*" and with Mulder's "*Syringa wax*," but the present investigation has shown that the wax contained in Truxillo coca, the broad-leaved South American coca, and in the small-leaved Java coca is not identical. To extract the wax the finely-ground coca is moistened with sodium carbonate solution, and then extracted with petroleum ether. The resulting solution is treated with sulphuric acid to remove the alkaloids and then distilled with the addition of water. The wax remains behind and is purified by repeated crystallisation from hot alcohol. That obtained from Truxillo coca consists of *palmityl- β -amyirin*, and melts at 75°C ., whilst the wax from the broad-leaved South American coca contains a ketone $\text{C}_{35}\text{H}_{70}\text{O}$ (β -*Cerettione*) in addition to the above ester. The wax melts at $69^{\circ}-70^{\circ}\text{C}$. Java coca wax melts at 77°C . and contains in addition to the above two substances which are readily soluble in cold ether, a mixture of bodies insoluble in cold ether, which was found to contain a *hydroxy-cerotic acid* $\text{C}_{27}\text{H}_{44}\text{O}_5$, *cerin*, the ceryl ester of cerotic acid, and *Myristyl- β -Amyrin*, the first of which most probably occurs as an ester. (*This Journal*, 1889, 131, 132, 133, 305, 567; 1890, 100, 541, 543, 599, 646, 1060; 1892, 177 (Geisel).)—C. A. K.

Carotin. O. Hesse. *Annalen*, 1892, 271, 229—230.

THE author throws doubt upon Arnaud's statement that carotin always accompanies chlorophyll (*Compt. rend.* 104, 1293), and considers his method of determining the colouring matter colorimetrically unreliable, especially as rubidin, another red colouring matter, has been shown by Negri to exist in various plants (*Gazz. Chem.* 9, 506). The insufficiency of the analytical data on which the proposed formula $\text{C}_{26}\text{H}_{34}$ is founded, is also referred to.

—C. A. K.

Antiseptics and Medicinal Products derived from Coal Tar, or from Aromatic Oils. A. Trillat. *Monit. Scient.* May 1892, 338—351.

AT the close of a series of articles on antiseptics and medicinal products the author gives the following table, in which a scientific classification is adopted, the phenols of the benzene series appearing first, being followed by naphthalene and the naphthols. Then come antiseptics, containing the carboxylic group, &c. Subsequently appear antiseptics containing nitrogen, commencing with acetanilide (antifebrin), these pass into pyridine, quinoline, and similar derivatives:—

Commercial Name.	Scientific Name and Formula.	Method of Formation.	Distinctive Properties.
Carbolic acid, phenol, phenic acid.	Phenol— $C_6H_5.OH$	By distilling tar	Melts at 44° . Slightly soluble in water, soluble in alcohol, ether, and alkalis. 20 parts of phenol and 10 parts of alcohol give with one part of ferric chloride a green coloration, which becomes violet on adding water. With lead acetate an abundant precipitate. With sulphuric acid no coloration; when the acid contains nitric acid a reddish-brown or greenish coloration. On introducing vapours of bromine into an aqueous solution of phenol, tribromophenol (m.p. 95°) is precipitated in colourless crystals.
Aseptol	An ill-defined mixture of phenyl ethers and sulphomated phenols.	By the action of sulphuric acid on phenol in presence of alcohol.	
Thymol	Propylmetacresol— $C_6H_3 \begin{cases} \text{CH}_3 \\ \text{C}_3H_7 \\ \text{OH} \end{cases}$	Extracted from essence of thyme.	Melts at 44° . Very sparingly soluble in water, soluble in alcohol and ether. 5 mgrms. of thymol, 1 cgr. of sodium nitrate, and 2 cc. of sulphuric acid, give a yellow coloration (nitrosotymol) which, after an hour, changes into a stable green coloration. When 1 part of thymol and 1 part of soda is treated with 10 parts of chloroform, a red unstable coloration. A caustic soda solution of thymol gives, when poured into a solution of potassium iodide in potassium iodate, a reddish-brown precipitate of aristol.
Sozoiodol	Sodium di-iodoparaphenol sulphate— $C_6H_2I_2 \begin{cases} OH \\ SO_2Na \end{cases}$	By the combination of sodium paraphenolsulphonate with iodine.	Soluble in alcohol, sparingly soluble in ether. Suspended in water and exposed to light gives a deposit of iodine after an hour. When warmed with nitric acid and the solution evaporated, gives picric acid and sulphuric acid.
Aristol, Amidaline	Di-iododithymol— $\begin{array}{c} C_3H_7 \\ \\ CH_3.C_6HI \begin{cases} OH \\ \\ CH_3.C_6HI \begin{cases} C_3H_7 \\ OH \end{cases} \end{cases} \end{array}$	By the combination of thymol with iodine.	Melts at 60° . Insoluble in water, soluble in chloroform with a red coloration. Heated in a closed tube, vapours of iodine evolved. Its alcoholic solution gives no coloration with ferric chloride in the cold; on evaporating, a black residue, soluble in chloroform with a brown coloration.
Europhen	Isobutylresolhydriodide— $\begin{array}{c} O.C_6H_3(C_4H_9).CH_3 \\ \\ HI \\ \\ O.C_6H_3(C_4H_9).CH_3 \end{array}$	By the combination of isobutylorthocresol with iodine.	Begins to soften at 70° . Insoluble in water and alkalis, soluble in alcohol and ether; in its alcoholic solution water produces a yellow flocculent precipitate. Separation of iodine on prolonged boiling with water, and on treating with sulphuric acid. Warmed with zinc dust gives iodide of zinc.
Resorcin	Resorcinol— $C_6H_4 \begin{cases} OH \\ OH \end{cases}$	By fusing sodium benzenedisulphonate with caustic soda.	Very soluble in water, alcohol, and ether, sparingly soluble in chloroform. Violet coloration with ferric chloride. No coloration with ferrous sulphate (distinction from pyrogallie acid). Sulphuric acid containing a trace of nitric acid gives a violet coloration. With chloral hydrate and caustic soda a red coloration.
Guaiacol	Monomethylpyrocatechol $C_6H_3 \begin{cases} OH \\ OCH_3 \end{cases}$	Extracted from the creosote obtained from beech wood.	Boils at 200° . Very sparingly soluble (1 in 200) in water but soluble in alcohol, ether, and alkalis. In aqueous solutions ferric chloride produces a brownish turbidity; in alcoholic solutions a fine blue coloration. Warmed with sulphuric acid it gives an orange coloration. On shaking 4cc. of guaiacol with milk of lime, containing 0.1 grm. of lime in 10 cc. of water, colourless crystals of a calcium derivative are formed.
Pyrogallol	Pyrogallol, pyrogallie acid. $C_6H_3 \begin{cases} OH \\ OH \\ OH \end{cases}$	By heating gallic acid	Fairly soluble in water and alcohol, only sparingly in benzene and chloroform. Gives with ferric chloride a yellow coloration, and with ammonium vanadate a yellow coloration which changes to brown. Potassium ferricyanide give crystals of purpurogallin on keeping for a day. Does not precipitate salts of quinine.
Naphthalene	Naphthalene— $C_{10}H_8$	Extracted from coal-tar.	Melts at 80° . Insoluble in water, soluble in alcohol and ether. Gives with sulphuric acid containing a trace of nitric acid a brown coloration. On gently warming a mixture of 1 cc. of sulphuric acid, 1 cc. of chloroform, and 0.05 grm. of naphthalene the sulphuric acid is coloured red, whilst the chloroform remains colourless. Gives with an alcoholic solution of picric acid crystals of naphthalene picrate, which are sparingly soluble in acids.
β -Naphthol	β -Naphthol— $C_{10}H_7 \begin{cases} OH \\ CH=CH \end{cases}$	By fusing α -naphthalene- β -sulphonic acid with caustic soda at a high temperature.	Melts at 123° . Sparingly soluble in water, soluble in alcohol, ether, and alkalis. Gives with sulphuric acid a reddish-yellow coloration. When agitated with milk of lime gives, after filtering, a highly fluorescent solution. When warmed with an alcoholic solution of picric acid, orange crystals are deposited on cooling. On adding 5 drops of caustic soda at 50° to a solution of 0.01 grm. of β -naphthol in 5 drops of chloroform the alkali turns blue.
α -Naphthol	α -Naphthol— $C_{10}H_7 \begin{cases} OH \\ CH=CH \end{cases}$	By fusing naphthalene- α -sulphonic acid with caustic soda.	Melts at 94° . Gives most of the reactions of β -naphthol. Its distinctive characters are:—On filtering a mixture of α -naphthol and milk of lime and then adding bromine-water there is produced a lilac coloration, which changes to violet. Two parts of α -naphthol, and 2 parts of mercuric chloride give a bright red precipitate when warmed with a solution of 1 part of sodium nitrate; under the same conditions β -naphthol gives an amorphous reddish-brown compound.

Commercial Name.	Scientific Name and Formula.	Method of Formation.	Distinctive Properties.
Meriodine	Chiefly composed of the sodium derivative of β -naphthol; also contains phenols.	By the action of caustic soda on β -naphthol at a high temperature.	Soluble in water with a slight fluorescence. Strongly alkaline reaction. When treated with sulphuric acid gives a precipitate of β -naphthol.
Benzoic acid.....	Benzoic acid— $C_6H_5.CO_2H$	By the action of nitric acid on chlorinated toluene.	Melts at 121° . Very sparingly soluble in cold water, more readily in alcohol and ether. Sublimes. Melted with caustic soda yields benzene and sodium carbonate. Gives formic acid on treatment with sulphuric acid and manganese dioxide.
Salicylic acid	Orthohydroxybenzoic acid $C_6H_4 \begin{cases} OH \\ COOH \end{cases}$	By the action of dry carbon dioxide on sodium phenate.	Melts at 156° . Sparingly soluble in water, soluble in alcohol and ether. With ferric chloride gives a violet coloration. No coloration with cold sulphuric acid, but on adding sodium nitrate, a red coloration is produced. With nitric acid, on warming, it gives a red coloration (nitro-salicylic acid). A solution of 0.16 gram. of salicylic acid and 0.11 gram. of borax in 1 cc. of water deposits crystals.
Salol.....	Phenol salicylate— $C_6H_5 \begin{cases} OH \\ COOC_6H_5 \end{cases}$	By the combination of phenol and salicylic acid.	Melts at 42° . Insoluble in cold water, but soluble in alcohol and ether. Gives with warm sulphuric acid a yellow coloration, but no reaction with nitric acid. When warmed with ammonia it gives a solution which is coloured violet by ferric chloride. A mixture of 0.05 gram. of salol and 0.08 gram. of sodium nitrate gives a greenish-blue coloration with 1 cc. of sulphuric acid; with sodium nitrite, instead of the nitrate, there is produced a red coloration, which first changes to brown and then to greenish blue.
Betol; naphthalol	β -Naphthol salicylate— $C_{10}H_7 \begin{cases} OH \\ COO.C_6H_5 \end{cases}$	By the combination of salicylic acid and β -naphthol.	Melts at 95° . Almost insoluble in water, and sparingly soluble in alcohol, but soluble in ether. With sulphuric acid and sodium nitrate it gives a greenish coloration; with sodium nitrite a reddish coloration. Is insoluble in warm caustic soda (distinction from salol). Gives with warm milk of lime, after filtering, a blue fluorescent solution which, after acidifying, is turned violet by ferric chloride.
Hydroxynaphthoic acid	Hydroxynaphthoic acid— $C_{10}H_7 \begin{cases} OH \\ COOH \end{cases}$	By the action of dry carbon dioxide on the sodium derivative of naphthol.	Melts at 186° . Sparingly soluble in water, soluble in alcohol and ether. With nitric acid gives a yellow coloration and liberation of carbon dioxide. Its potassium salt gives a blue coloration with ferric chloride.
Dermatol	Sub-gallate of bismuth— $C_7H_7O_7Bi$	By the action of bismuth nitrate on gallic acid.	Insoluble in water, alcohol, and ether. When ignited it gives a residue containing bismuth.
Hypnone	Acetophenone, methyl phenyl ketone— $CH_3.CO.C_6H_5$	Produced by the dry distillation of a mixture of benzoate and acetate of calcium.	Melts at 245° . On oxidation with sulphuric acid and potassium bichromate gives benzoic acid and carbon dioxide. Warmed with sulphuric acid it yields benzoic acid. Warmed with ammonium sulphide it gives phenyl-acetic acid.
Benzosol.....	Benzoylbenzylalcol— $C_6H_5 \begin{cases} OCH_3 \\ O.CO.C_6H_5 \end{cases}$	By the combination of benzoyl chloride and guanacol.	Melts at 50° . Almost insoluble in water, and only sparingly soluble in acetic acid, but soluble in alcohol and chloroform.
Benzoylnaphthol	Benzoylnaphthol— $C_{10}H_7O.CO.C_6H_5$	By the combination of benzoyl chloride and β -naphthol.	Melts at 110° . Sparingly soluble in water, soluble in alcohol.
Antifebrin	Acetanilide— $C_6H_5.NH.CO.CH_3$	By the action of acetic acid on aniline.	Melts at 118° . Sparingly soluble in water, soluble in alcohol and ether. On warming a mixture of 0.1 gram. of acetanilide, 1 cc. of caustic soda, and 3 drops of chloroform the disagreeable smell of phenyl isocyanide is emitted. With nitrate and nitrite of sodium a red coloration. No reaction with cold nitric acid, an orange coloration on warming.
Exalgin.....	Methylacetanilide— $C_6H_5.N \begin{cases} CH_3 \\ CO.CH_3 \end{cases}$	By the action of acetyl chloride on monomethylaniline.	Melts at 162° . Sparingly soluble in water, soluble in alcohol. Does not yield phenyl isocyanide when warmed with chloroform and caustic soda. Its solution in sulphuric acid gives a yellowish green coloration on the addition of sodium nitrate.
Phenacetin ..	Acetylparaphenetidine— $C_6H_4 \begin{cases} OC_2H_5 \\ NH.CO.CH_3 \end{cases}$	By the combination of paramidophenetol and acetic acid.	Melts at 135° . Very sparingly soluble in cold water, more readily in alcohol. No coloration with ferric chloride. Dissolves in sulphuric acid, giving, when pure, a colourless solution. A mixture of equal parts of phenacetin and sodium nitrite gives with sulphuric acid a violet coloration, which changes to green. When warmed with zinc dust yields salicylic acid. With caustic soda and chloroform it gives phenyl isocyanide.
Phenocoll hydrochloras	Amidoacet paraphenetidinehydrochloride— $C_6H_4 \begin{cases} CO.C_2H_5 \\ NH.CO.CH_3.NH_2 \end{cases} (HCl)$	By the action of ammonia on the compound obtained from paraphenetidine and acetyl chloride.	Carbonises at about 200° . Soluble in 18 parts of water. Gives most of the colour reactions of phenacetin. Dissolves in sulphuric acid with a yellow coloration; on adding sodium nitrate a brownish-red coloration. Its solutions are precipitated by a solution of iodine. Gives with mercuric chloride and sodium nitrate a yellow amorphous precipitate.

Commercial Name.	Scientific Name and Formula.	Method of Formation.	Distinctive Properties.
Salophen	Acetylparamidophenol salicylate— $\begin{array}{c} \text{OH} \\ \\ \text{C}_6\text{H}_4 \\ \\ \text{COO.C}_2\text{H}_5.\text{NH.CO.CH}_3 \end{array}$	Salicylic acid is treated with phosphorus oxychloride and paramitro-phenol; the product is reduced and then acetylated.	Melts at 188° . Sparingly soluble in cold, more readily in hot water; soluble in alcohol and ether.
Sulphaminol	Thiohydroxydiphenyl- amine— $\text{OH.C}_6\text{H}_5 \begin{array}{c} \diagup \text{N} \diagdown \\ \text{S}_2 \end{array} \text{C}_6\text{H}_5$	By the combination of sulphur with methahydroxydiphenylamine.	Melts at 133° . A yellow, amorphous, tasteless, odourless powder, insoluble in water, but soluble in alcohol, alkalis, and glacial acetic acid. Gives a blue coloration with nitric acid. The presence of sulphur can be easily detected.
Saccharine	Saccharine— $\text{C}_6\text{H}_4 \begin{array}{c} \diagup \text{CO} \diagdown \\ \text{SO}_2 \end{array} \text{NH}$	By the oxidation of toluenesulphonamide.	Melts at 226° . Fairly soluble in hot water, soluble in alcohol and ether. No coloration with ferric chloride. When warmed with potassium carbonate gives a smell of bitter almonds. Treated with lime it gives ammonia. When heated with solid sodium acetate vapours are evolved which blacken paper moistened with lead acetate; the residue, after solution in nitric acid, gives a precipitate of barium sulphate on the addition of barium nitrate.
Benzoylamidophenyl- acetic acid.	By treating amido-phenylacetic acid with benzoyl chloride.	Melts at 175.5° .
Hydracetic, pyrodon ..	Acetylphenylhydrazine— $\text{C}_6\text{H}_5.\text{NH.NH.CO.CH}_3$	By the combination of phenylhydrazine and acetic acid.	Melts at 128° . Sparingly soluble in water. Reduces Fehling's solution in the cold. Gives a blue precipitate with ferric chloride and potassium ferri-cyanide. With sulphuric acid containing nitric acid it gives a carmine-red coloration.
Iodol	Tetridopyrroline— $\text{NH} \begin{array}{c} \diagup \text{Cl} \diagdown \\ \text{Cl} \end{array}$	By the combination of iodine and pyrroline.	Decomposes at 110° . Insoluble in water, soluble in alcohol and ether. Gives a black precipitate with mercuric chloride. When treated with hydrochloric acid, iodine is liberated. With alcohol and ferric chloride it gives a greenish-blue coloration.
Pyridine	Pyridine— $\text{C}_5\text{H}_5\text{N}$	Formed by the dry distillation of nitrogenous matter.	Boils at 111.8° . Miscible with water. Gives a crystalline precipitate with a solution of iodine in potassium iodide, and abundant precipitates with bromine water and with tannic acid. With mercurous chloride in the cold it yields a crystalline substance.
Quinoline	Quinoline— $\text{C}_9\text{H}_7\text{N}$	By heating aniline with glycerol and sulphuric acid.	Boils at 238° . Sparingly soluble in water, soluble in alcohol. Gives with mercury cyanide a crystalline precipitate, soluble in hydrochloric acid. Gives with mercurous chloride a grey coloration, and with bromine water an abundant precipitate. Precipitates the hydrates of the metals from solutions of copper sulphate and of alum.
Thallin	Sulphate of tetrahydro- paraquinanisol— $\text{C}_9\text{H}_{10}\text{N.OCH}_3$	By reducing paraquinanisol.	Melts at 106° . Gives with chlorine water a green coloration and a flocculent precipitate; after a very short time the coloration becomes violet. No coloration with sulphuric acid and nitric acid. Is precipitated from its solutions by ammonia. With ferric chloride it gives, after an hour's time, a green coloration which first changes to red, then to brown. Potassium ferri-cyanide produces first a green and then a red coloration.
Kaërin	Tetrahydrohydroxymethyl- quinoline— $\text{C}_9\text{H}_9\text{N} \begin{array}{c} \diagup \text{OH} \diagdown \\ \text{CH}_3 \end{array}$	By reducing hydroxy-quinoline with tin and hydrochloric acid and then methylating.	Gives the same reactions as thallin.
Orexin	Phenyldihydroquinazoline hydrochloride— $\text{C}_6\text{H}_4 \begin{array}{c} \diagup \text{CH}_2.\text{N.C}_6\text{H}_5 \diagdown \\ \text{N} : \text{CH} \end{array} \quad \text{HCl} + 2 \text{H}_2\text{O}$	By reducing ortho-nitrobenzylformanilide.	Melts at 86° . Fairly soluble in methyl alcohol, sparingly in ether. Gives precipitates with ammonia and with acids. When treated with sodium nitrite and sulphuric acid, it gives a brown coloration which changes to green; with sodium nitrate, first a red and then a yellow coloration.
Antipyrin	Dimethylphenylpyr- azalone— $\begin{array}{c} \text{C}_6\text{H}_5 \\ \\ \text{CO}-\text{N} \\ \quad \diagup \quad \diagdown \\ \text{CH}=\text{C} \quad \text{N}-\text{CH}_3 \\ \\ \text{CH}_3 \end{array}$	By methylating the product of the action of phenylhydrazine on ethyl-aceto acetate.	Melts at 113° . Fairly soluble in water and alcohol, insoluble in carbon bisulphide. Dissolves in acids yielding colourless solutions. Gives with sodium nitrite and acetic acid a greenish-blue coloration, and then nitrosoantipyrin. With ferric chloride a flocculent precipitate, which dissolves in alcohol with a red coloration.

A Simple Extraction and Condensing Apparatus
K. Farnsteiner. Chem. Zeit. 16, 1030.

See under XXIII., page 1034.

PATENTS.

Improvements in Obtaining or Separating Oxygen from Atmospheric Air. J. H. Parkinson, Stretford. Eng. Pat. 14,925, September 22, 1890.

A REPRINT of a former specification (this Journal, 1891, 947) in consequence of an amendment made by the Comptroller, the inventor now claiming the use only of a spongy mass of potassium or sodium permanganate "or lower oxides thereof" for this purpose.—J. G. W.

Manufacture of Vanilloyl Carbonic Acid and of Vanilline by its Transformation. O. Imray, London. From La Société de Laire et Cie., Paris. Eng. Pat. 17, 137, October 8, 1891.

When acetylugenol—

or acetyl-iso-eugenol—

is oxidised for the production of vanilline, a substance to which the name of vanilloyl carbonic acid is given, is formed. Crude vanillin often contains this body which can be separated by agitating an ethereal solution of the mixture with water containing magnesium carbonate or a carbonate of the alkaline earths in suspension, or with a solution of sodium or of potassium bicarbonate, when a soluble salt of the acid is formed. Another method of separation is to fractionally precipitate the aqueous solution of the compounds of the two bodies with alcohol, when that of the acid separates first. The acid dissolves in ether and can be crystallised from benzene. It melts at 134° C. and has the formula $\text{C}_6\text{H}_5 \cdot (\text{CO} \cdot \text{CO} \cdot \text{OH}) \cdot \text{OCH}_3 \cdot \text{OH}$. When heated vanillin and carbonic acid result.—C. A. K.

Improvements relating to the Manufacture of Perfumes. R. A. Chesebrough, London. Eng. Pat. 20,851, November 30, 1891.

The invention consists in forcing perfume-laden air surrounding flowers, growing plants or other odoriferous substances into vessels containing a suitable absorbent such as alcohol. The perfume is thus obtained free from the contaminating effect of the scent of any juices or decay that may have taken place amongst crushed or dead leaves.

—C. A. K.

Improvement in the Production of Pure Saccharine. C. Fahlberg, Salbke, near Magdeburg, Prussia. Eng. Pat. 22,787, December 30, 1891.

CRUDE saccharine, as prepared according to the inventor's previous patent (Eng. Pat. 6626, 1885; this Journal, 1885, 608), consists of a mixture of 60 per cent. anhydro-orthosulphamine-benzoic acid (ortho-acid) and 40 per cent. parasulphamine-benzoic acid (para-acid), the sweetening power of the former being 40 per cent. greater than that of the latter. The separation of the two has heretofore presented considerable difficulty owing to the solubility of the acids and their salts, in water and other solvents, being nearly the same.

This is a method for effecting the separation of the two, based on the fact, discovered by the inventor, that the ortho-acid has a greater affinity for the alkalis and alkaline earths than the para-acid. The process may be conducted in two ways; first, to a concentrated solution of the alkaline salts of the two acids, a mineral acid (HCl), or the ortho-acid, or a mixture of the ortho- and para-acids (crude saccharine) is added in quantity sufficient to displace

the para-acid from its salt. The para-acid separates out, leaving the salt of the ortho-acid in solution. In the other method, dry, crude saccharine is added to a solution of an alkali or an alkaline carbonate, containing a sufficient quantity to neutralise the ortho-acid, which dissolves, forming its alkaline salt, and leaving the para-acid unacted upon. From the solution of its alkaline salt, the ortho-acid, or pure saccharine, is obtained by acidulation with a mineral acid.—J. G. W.

Improved Process for Extracting Iodine from Natural Saline Waters, Mother Liquors, or other Liquids containing Iodine. W. P. Thompson, Liverpool. From R. Campani, Pisa, Italy. Eng. Pat. 16,942, September 22, 1892.

A PROCESS for extracting pure iodine from saline liquors, without previous concentration, by means of iodide of starch. Starch paste is added to the liquor and then a sufficient quantity of bleaching-powder solution to liberate the whole of the iodine. After standing ten hours, the precipitate of iodide of starch is filtered off, washed and treated with sulphurous anhydride, forming hydriodic acid and leaving a deposit of starch, which can be used again. The solution of hydriodic acid, containing a little sulphuric acid, is neutralised with sodium carbonate, and the iodine then liberated by potassium bichromate and sulphuric acid in a sufficiently pure state to dispense with sublimation.

—J. G. W.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

A New Process for Photo Dyeing. A. Villain. L'Amateur Photographe, 1892.

THIS process is based on the experiments of Kopp. The sensitive salt used is bichromate of ammonia, to which is added a little meta-vanadate of ammonia, this being a more energetic mordant.

The composition of the sensitising bath is as follows:—

Water	1,000 cc.
Bichromate of ammonia	50 grms.
Meta-vanadate of ammonia	5 grms.

After immersion the tissue is dried at a low temperature 25—30° C., away from all white light. After exposure under a negative the details appear clearly defined, the print is then thoroughly washed to remove all traces of the unaltered salts, and in this state it may be dried and preserved, it being merely sufficient to steep in warm water before dyeing. The print having been placed in the dyeing-bath, which is heated to boiling for 10 or 15 minutes, is taken out and washed; if the whites are then not pure the print is passed through a warm bath of carbonate of soda, or a cold bath of chloride of lime to which a few drops of hydrochloric acid have been added. After a thorough washing the print is finished.

The colouring matters chiefly used are: artificial alizarin, alizarin blue S, alizarin black S, alizarin black R, galloflavin, purpurin, anthracene blue, alizarin orange, cerulein S, gallein, alizarin green, alizarin yellow, alizarin maroon, &c.

The prints thus obtained offer great resistance to the action of light, alkalis, and acids.—J. C. C.

PATENTS.

The Preparation and Employment of Aromatic Amido Compounds as Developing Means in Photography. J. Hauff, Stuttgart, Germany. Eng. Pat. 15,434, September 11, 1891.

THE amido phenols used for developing have to be used in caustic alkali solution, which is in many ways unsuitable in practice. By substituting the hydrogen of the amido group by alkyl groups this objection is avoided, as the resulting bodies can be employed in solutions of the alkaline carbonates. The specification covers the preparation of the following bodies:—Mono- and di-methyl and ethyl derivatives of para-amidophenol, ortho-amido-meta-cresol, meta-amido-ortho-cresol, meta-amido-metaxylonol, meta-amido-para-xylonol, ortho-amido-ortho-xylonol and ortho-amido-meta-xylonol (Sym.), also mono-, di-, and tetra methyl or ethyl derivatives of para-phenylenediamine, para-tolylene diamine, para-xylylenediamine, α - β -naphthylene diamine and α - α -naphthylene diamine. Suitable developing mixtures containing the above substances are given.

—C. A. K.

A New Apparatus for Developing, Fixing, and Washing of Photographic Dry Plates without the use of a Dark Room. L. Nievsky, London. Eng. Pat. 17,860, October 19, 1891.

THE plate after exposure is dropped from the camera into a light tight tank provided with red glass windows; the bottom of this tank is connected by three or more tubes to india-rubber balls containing developing solution, washing water, fixing solution, &c. To develop the plate, the tap opening to the ball containing the developing solution is opened and the ball compressed so as to cause the liquid to rise in the tank and cover the plate, when developed the pressure on the ball is relieved and the solution so withdrawn. The plate is then treated in a similar manner with fixing solution, &c.—J. C. C.

Apparatus for Developing, Fixing, and washing Photographs. J. Wagner and G. Bredig, Leipzig, Germany. Eng. Pat. 19,471, November 10, 1891.

THIS apparatus is in the form of a shallow rectangular box, placed upright on its narrow side, and divided into two parts by a perforated division. The front and back are provided with red glass windows and a lid closes it hermetically. The liquid is admitted through a tap-funnel placed at the top of the box and communicating with the lower division which has in addition a draw-off cock. The plate having been introduced into the box, rests with its lower edge on the division plate and the cover is put on; the developing solution is then poured into the lower division by means of the funnel and the tap closed. The box is then turned upside down, the solution running over the plate. In order to examine the plate or run off the solution the position is reversed. In the same manner the plate may be fixed and washed.—J. C. C.

Improvements in Apparatus or Appliances for Use in Drying Sheets of Glue, Gelatin, and the like. W. P. Thompson, Liverpool. From F. Krauseder, and A. Leutsch, Munich, Germany. Eng. Pat. 20,755, November 28, 1891.

See under XIV., page 1018.

XXII.—EXPLOSIVES, MATCHES, Etc.

PATENTS.

Improvements in Explosive Compounds. H. E. Newton, London. From A. Nobel, Paris, France. Eng. Pat. 4179, December 2, 1875. (Second Edition.)

By this invention nitroglycerin or other analogous substance is gelatinised by dissolving in it collodion cotton. The solution of this body may be effected directly by heating the two substances together or the collodion cotton may be first dissolved in a "promoting" solvent, such as acetone &c., and the solution mixed with the nitroglycerin. On evaporating the solvent an explosive jelly is left. Suitable proportions are seven parts of collodion cotton and 93 parts of nitroglycerin. The rate of explosion of this gelatin may be decreased and regulated by incorporating with it from half to thirty per cent. of acetic ether or nitrobenzol &c.

Cheaper explosives may be made by mixing the gelatin with, for instance, sawdust and a nitrate.—W. M.

Preparation of Explosive Compounds. A. V. Newton, London. From A. Nobel, Paris, France. Eng. Pat. 226, January 20, 1879. (Second Edition.) (Provisional protection only.)

It is proposed to produce powders of any desired quickness of explosion, by mixing a comparatively slow gunpowder with a quick powder in such proportions as to produce the quickness of explosion needed.—W. M.

Manufacture of Explosive Compounds. H. E. Newton, London. From A. Nobel, Paris, France. Eng. Pat. 2599, June 17, 1879. (Second Edition.)

"THIS invention relates to a method of imparting to highly compressed meal, in contradistinction to grained, gunpowder, that quickness of explosion which it needs to become useful as a blasting agent, and which also facilitates its adaptation as a propelling agent in heavy guns."

Special primers consisting of a small charge of harium or lead picrate, or analogous fulminate equally insensible to percussion, are used in conjunction with cartridges of compressed meal powder. The firing of such primer serves to explode the sluggish meal powder which cannot be exploded in the ordinary way.—W. M.

Improvements in or relating to the Manufacture of Explosive Substances. W. P. Thompson, Liverpool. From E. Landener, Paris, France. Eng. Pat. 19,267 November 7, 1891.

THE improvements consist in coating chlorates with fatty substances, hydrocarbons and their nitric derivatives, for the purpose of rendering them less sensitive to concussion, and insoluble in water, whilst entirely preserving their shattering properties.—W. M.

An Improved Explosive Compound. W. E. Gedge, London. From the United States Smokeless Powder Company, San Francisco, U.S.A. Eng. Pat. 12,415, July 5, 1892.

THE new explosive is a mixture of picrate and nitrate of ammonia with or without nitroglycerin. The proportions are varied according to the explosive force required. One

part of picrate of ammonia with one part of nitrate of ammonia will form a very quick and powerful explosive, and the violence may be varied by increasing the proportion of nitrate of ammonia up to nine parts to one of picrate. For blasting purposes, nitroglycerin is added; if 4 parts of picrate of ammonia and 6 parts of nitrate of ammonia have been used, six parts of nitroglycerin will make an effective mixture. The picrate and nitrate are mixed in any suitable manner, and the nitroglycerin added and mixed in.

—A. G. B.

ADDENDUM.

In the No. 3 of this Vol. XI., page 235, col. 2, the article on the *Preparation of α -Trinitrotoluene*, C. Häussermann, should be referred to under XXII., Explosives, to which Group the substance properly belongs.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS.

Improvements in the Gasvolumeter. G. Lunge. Ber. 25, 3157—3164.

In this article the author describes some improvements that he has made in his well-known "gasvolumeter" which was described in the *Berichte*, 1890, 449 (this Journal, 1890, 547—549; and 1891, 1031).

Having found that every form of glass tap to the "reduction" tube that he has tried, sooner or later ceased to be gas-tight, and that the alternative plan of sealing off the drawn-out end of the reduction tube is somewhat inconvenient, if through some mishap, or for other reason it becomes necessary to readjust the volume of air in the reduction tube, he has now devised two plans of closing the reduction tube, in such a manner as to ensure a permanently gas-tight closure under either increased or diminished pressure, whilst at the same time they allow of the ready opening of the tube for the purpose of readjusting it when desirable. The first method consists in drawing out the upper end of the reduction tube to a capillary with a stout wall, and with a slight bulge on it (see Fig. 1). The end of the tube is ground square, and a piece of glass rod of the

same thickness as the tube and with a slight bulge on it also is ground square to meet it. A piece of india-rubber tube is slipped over the bulge on the capillary leaving an equal length projecting above the top of the capillary, and the level of the mercury in the reduction tube is then brought to the division on the tube that allows of 100 cc. of dry air at the temperature and pressure of the day entering the tube. A drop of mercury is then poured into the india-rubber tube, the glass-rod is inserted and the india-rubber tube tied with wire and varnished. Fig. 2 shows the second method of closing the tube, which the author considers even more satisfactory than that already described. The reduction tube in this case is widened out at the top into a cup, a stout-walled neck forming the connection. A somewhat conical, thin, glass stopper is accurately ground into this neck. This stopper is well coated with vaselin or paraffin so that it does not seize, and so that it may also close the tube more perfectly. In the lower half of the stopper a vertical groove is cut, so that on turning the stopper this groove may be made to connect with a corresponding groove cut in the upper part of the neck. When the two grooves connect together a small air channel is formed, but on turning the stopper round the passage is at once closed. After adjusting the volume of air in the tube and closing it by turning the stopper, mercury is poured into the eup. To make the seal still more secure and to prevent mercury in the eup from being thrown out by any chance, a cork with a small tube passing through a perforation in it is inserted into the eup and pressed down upon the top of the glass stopper, and bound down, the small tube through the cork, allowing the mercury to enter it and so giving room for expansion and contraction under changes of temperature.

The author further states that he now has the reduction tube graduated somewhat differently to the usual form. Instead of making the tube so that the 100 cc. division comes immediately below the wider part of the tube it is made so that the 95 cc. division comes there and the graduation is continued down the narrow tube up to 125 cc., the length of tube for each cubic centimetre being as nearly as possible 10 mm. By this arrangement a volume of dry gas can very readily be measured against a volume of damp gas in the reduction tube, and vice versa,—operations which are frequently convenient.

The author pointed out how this might be done some time ago (*Zeits. angew. Chem.* 1891, 410; this Journal, 1891, 1031), viz., by placing the reduction tube filled with damp air, when measuring a volume of dry gas, *lower*, and when filled with dry air for measuring a volume of damp gas, *higher* than the normal position by as many millimetres as correspond to the tension of water vapour at the existing temperature. To do this, however, requires the use of a measure which by the new arrangement is avoided. For instance, if it be desired to measure a volume of dry gas at a temperature of 15° against a moist reduction tube, the levelling tube is so placed that the mercury in the reduction tube stands at 100°, but instead of bringing the mercury in the gas-measuring tube on a level with this point it must be brought on a level with the division 98.7° of the reduction tube, the difference between 100° and 98.7 being 13 mm., which is approximately the tension of water vapour at the temperature of 15° (more exactly 12.7 mm.). There is, therefore, in the gas measuring tube a column of mercury 13 mm. higher than that in the reduction tube, in other words the dry gas is compressed more than the damp air in the reduction tube by an amount exactly corresponding to the tension of the water vapour in the latter. Obviously, if it be desired to measure a damp gas against a dry reduction tube, the level of the mercury in the measuring tube must be brought as many millimetres lower than the level of the mercury in the reduction tube as corresponds to the existing tension of water vapour. Moreover, the same result can be arrived at by adjusting the mercury in the reduction tube at so many millimeters higher or lower than 100° as corresponds to the tension of water vapour at the time and then bringing the mercury in the gas measuring tube on a level with the 100° division on the reduction tube.

Fig. 1.

Fig. 2.

Fig. 3.

The new method of graduation from 95 cc. to 125 cc. suffices for all ordinary purposes as a tension of water-vapour exceeding 30 mm. has never to be dealt with. If, however, it be desired to read off directly the weight in milligrammes instead of the volume of gases, the reduction tube must be graduated from 90 cc. to 150 cc. In a tube so graduated the operation is conducted as follows:—

Instead of bringing the level of the mercury in the reduction tube to the 100th division, it must be brought to the division corresponding to the weight of 1 litre of the gas to be measured $\times 100$, e.g.—

For air it must be brought to.....	129.4
For oxygen „ „	113.0
For nitrogen „ „	125.5
For nitric oxide „ „	131.3

When the graduations of the tube do not extend far enough, the mercury in the reduction tube can be placed at the division corresponding to one-half or one-third the product, e.g., in the case of carbonic acid, instead of adjusting the mercury to 196.6°, it must be adjusted to 98.3°, and then each cubic centimetre in the gas-measuring tube = 2 mgrms.

This principle can be further extended. Instead of taking into account the weight of one litre of the gas to be measured, the weight of the substance actually sought for by the analysis may be read; as, for instance, in the case of bleaching powder when decomposed by hydrogen peroxide, each molecule of oxygen, O_2 , generated corresponds to one molecule of available chlorine, Cl_2 . By adjusting the reduction tube to the division corresponding to one-third the weight of 1 litre of chlorine $\times 100 = 105.6$ then each cc. of oxygen generated = 3 mgrms. of chlorine. In the azotometrical estimation of nitrogen, the usual correction of $2\frac{1}{3}$ per cent. must be made, so that the reduction tube must be adjusted to the division $\frac{125.5 \times 100}{97.5} = 128.7$; or if it be desired to read off the corresponding weight of ammonia, then it must be adjusted to the division $\frac{125.5 \times 17 \times 100}{14 \times 97.5} = 156.3$; in the case of urea the correction of 8 per cent. must be made and the product divided by 2, thus $\frac{125.5 \times 60 \times 100}{28 \times 92 \times 2} = 146.2$, when each cc. of gas = 2 mgrms. of urea. In order to read off the weight of calcium carbonate directly from the volume of carbonic acid, the reduction tube must be adjusted to the division $\frac{196.6 \times 100}{44 \times 4} = 111.7$, when each cc. of CO_2 corresponds to 4 mgrms. of $CaCO_3$; or again, if the weight of chlorine is required (as in iron analyses), the reduction tube is adjusted according to the calculation $\frac{196.6 \times 12 \times 2}{44} = 107.2$, in which case each cc. of CO_2 = 0.5 mgrm. of Cl.

The author remarks, however, that this lengthened form of reduction tube is not so convenient as the shorter form, and moreover the same results can be arrived at more readily with the latter, by taking certain definite weights of the substance to be examined and reading off at once the percentages sought for, as he has already shown (Zeits. ang. Chem. 1890, 143); whilst for any special kind of determinations, such as vapour density determinations and nitrogen estimations in organic substances, specially-graduated forms of the instrument may be advantageously used.

He calls attention also to a modified form of levelling tube, shown in Fig. 3, which effects an economy of mercury, and to a new iron stand by which, through a combination of a thin steel cord, a pulley, drum, and handle, the levelling and reduction tubes can be readily raised or lowered. (See also this Journal, 1891, 1029—1030.)

—H. S. P.

A Simple Extraction and Condensing Apparatus. K. Farnsteiner. Chem. Zeit. 16, 1039.

THE extraction apparatus depicted below may be readily constructed by the chemist.

The bent tube B B has a total length of 60 cm. and is 0.5 cm. wide; it serves as a condenser, a stream of water passing through it. The tube C, in which the substance to be extracted is contained, is 10 cm. long and 2 cm. wide, and rests on the wire spiral placed in the neck of the large tube A. This latter is 32 cm. in length and 3 cm. broad. The holder C is widened at four points at its upper part A, in order more effectually to catch the liquid falling from B.

—W. J. P.

Apparatus for Fractional Distillation. M. Ekenberg Chem. Zeit. 16, 958—959.

THE author has devised an apparatus for the fractional distillation of liquids boiling between 100° and 250°. The construction of the apparatus will be understood from the Figure on next page.

The fractionation column, 900 mm. in length and 4—5 mm. in diameter, is contained in a closed air-bath and is coiled round the glass cylinder which serves as a chimney. The temperature of the bath is regulated by a Stuhl's contact thermometer connected with an electrical thermo-regulator. The temperature of the jacket may be controlled within 0.2° C., and the difference in temperature between its upper and lower parts is only 0.5°. Sample distillations are quoted to demonstrate the great efficiency of the apparatus. It is especially recommended in technical laboratory estimations of xylenes, cumenes, solvent naphthas, anilines, nitrobenzenes or petroleum, &c.—W. J. P.

PATENT.

An Improvement in Analytical and other Delicate Balances also applicable to other Beam Weighing Machines.
G. P. Bidder, London. Eng. Pat. 21,186, December 4, 1891.

THE object of this invention is to supersede the use of "riders" on analytical balances. The invention consists in employing a flexible filament, thread, or light chain, of as nearly as possible uniform section throughout, one end of this chain being fixed to and suspended from one arm of the balance, preferably near the fulcrum, from which point the chain hangs in the form of catenary, the other end being led up through the top of the case and attached to an appliance for raising or lowering it; this may consist of a cylinder around which the chain is wound, and to which is attached a milled head and graduated circle moving past a fixed index; or the end of the chain may be attached to a vertically sliding bar marked with a scale, and worked by a rack and pinion, or by any suitable means.—J. C. C.

INORGANIC CHEMISTRY.—
QUANTITATIVE.

Nickel Analysis. S. H. Emmens. Eng. and Mining. J., November 26, 1892, 510—511.

THE substances usually submitted to analysis for the determination of the contained nickel may conveniently be classified as follows:—

1. Regulus and minerals containing arsenic, viz., speiss and arseniferous ores of nickel. 2. Regulus and minerals

containing no (or but little) arsenic, viz., matte, nickeliferous, pyrrhotite and non-arseniferous ores of nickel. 3. Metallic nickel, nickel steel, German silver, and other alloys of nickel.

In the absence of any generally recognised and accepted system of accurate nickel analysis, Mr. Charles T. Mixer, the chemist of the Emmens Metal Company, has, in conjunction with the author devised the following methods, which were found to be sufficiently trustworthy for all technical and commercial purposes.

METHOD A.—FOR SUBSTANCES HIGH IN NICKEL AND LOW IN COPPER AND IRON, *e.g.*, METALLIC NICKEL, BESSEMERISED MATTE, NICKEL OXIDE, &c.

Operation.	Reagent.	Separation.
1. Dissolve (about 2 grms.) and evaporate.	HNO ₃ + HCl, or fusion with KHSO ₄	..
2. Dissolve and filter	HCl + H ₂ O	SiO ₂ , C. &c.
3. Precipitate and filter	H ₂ S	CuS
4. Dissolve the washed precipitate and evaporate till white fumes are produced.	HNO ₃ + H ₂ SO ₄	..
5. Dissolve and electrolyse ..	H ₂ O + HNO ₃	Cu
6. Boil, filtrate from 3 and peroxidise.	HNO ₃	..
7. Cool and make solution up to 100 cc.	H ₂ O	..
8. Boil half of 7, precipitate and filter.	NH ₃	..
9. Redissolve the precipitate.	HCl	..
10. Precipitate and filter	NH ₃	..
11. Dissolve and reduce the well-washed precipitate.	H ₂ SO ₄ + Zn	..
12. Titrate	KMnO ₄	Fe
13. Precipitate and filter one-tenth (10 cc.) of 7.	NaHO	..
14. Dissolve the washed precipitate.	Dilute H ₂ SO ₄	..
15. Make alkaline.....	NH ₃	..
16. Electrolyse	Ni + Co

METHOD B.—FOR SUBSTANCES HIGH IN IRON AND LOW IN NICKEL, *e.g.*, PYRRHOTITE AND ONCE-RUN MATTE.

Operation.	Reagent.	Separation.
1. }		
2. }		
3. }		
4. }	Same as in Method A... Cu
5. }		
6. }		
7. Precipitate and filtrate ...	NH ₃	Fe ₂ O ₃ .H ₂ O
8. Boil the washed precipitate and redilute.	H ₂ O made faintly acid with H ₂ SO ₄ or HCl	Fe ₂ O ₃ .H ₂ O
9. Precipitate and filter	NH ₄ Cl + NH ₃	Fe ₂ O ₃ .H ₂ O
10. Add together the filtrates from 7 and 9; evaporate to small bulk; precipitate and filter.	NaHO in large excess	..
10. Dissolve the washed precipitate.	Dilute H ₂ SO ₄	..
11. Make alkaline.....	NH ₃	..
12. Electrolyse	Ni + Co

METHOD C.—Qualitative examination of pyrrhotite and other lean ores of nickel.

1. Reduce to fine powder.

2. Dissolve in *aqua regia*; evaporate to dryness; dissolve in HCl and H₂O; filter off from gangue and insoluble matter.

3. Pass H₂S through the solution to remove Cu.

4. Boil free of H₂S; peroxidise with HNO₃.

5. Precipitate the Fe with NH₃; boil; add HCl until the supernatant liquid is faintly acid; boil sharply for 10 minutes.

6. Make strongly alkaline with NH₃ and note the colour of the supernatant solution. If it be distinctly blue the percentage of nickel in the ore is commercially important.

7. If the solution be colourless, filter and boil down to a small bulk free from the odour of NH₃. Then add a few

drops of a solution of potassium sulphocarbonate, which will give a pink coloration if there be any trace of nickel in the ore.

N.B.—Test 7 is also useful for determining when the electrolytic separation of the Ni is complete in methods A. and B. It was found that the reaction is best observed when the solutions are neutral instead of being alkaline as recommended in the text-books.

A distinguished feature of the process is the treatment of the precipitated ferric hydroxide with a minute quantity of acid. This has the effect of dissolving any Ni or Co hydrate that may have been carried down with the iron; and it is more efficient than the numerous tedious and troublesome repetitions of solution, precipitation, filtration, and washing necessitated by the older methods. At first sight, indeed, it may be doubted whether sulphuric or hydrochloric acid will unite with nickel in preference to iron, seeing that the latter metal oxidises more energetically than the former; but the following thermo-chemical data will make the matter clear:—

Reaction.	Heat generated per Formula Weight.
	Units.
$\text{Fe} + \text{O} + \text{SO}_3\text{Aq} \dots\dots\dots$	93,200
$\text{Ni} + \text{O} + \text{SO}_3\text{Aq} \dots\dots\dots$	86,950
$\text{Fe} + \text{Cl}_2 + \text{Aq} \dots\dots\dots$	99,950
$\text{Ni} + \text{Cl}_2 + \text{Aq} \dots\dots\dots$	93,700
$\text{Fe} + \text{O} + \text{H}_2\text{O} \dots\dots\dots$	68,280
$\text{Ni} + \text{O} + \text{H}_2\text{O} \dots\dots\dots$	60,840

It results from these figures that the heat of formation of one molecule of ferrous sulphate by the union of ferrous hydroxide and dilute sulphuric acid is $93,200 - 68,280 = 24,920$ units; while that of nickel sulphate formed by the union of nickel hydrate with dilute sulphuric acid is $86,950 - 60,840 = 26,110$ units. Under these conditions, therefore, Berthelot's law of maximum work calls for the formation of nickel sulphate in preference to ferrous sulphate. If HCl be the acid, the figures are:—

Formation of nickel chloride.... $93,700 - 60,840 = 32,860$ units.
Formation of ferrous chloride... $99,950 - 68,280 = 31,670$ units.

In the particular case under consideration, the replacing power of nickel is still more marked, as, owing to the iron being peroxidised, its basic efficiency is lessened. The heat values per formula weight of acid, as given by Berthelot (*Mécanique Chimique*, tome 1, 384) are:—

	Units.
Formation of ferric chloride.....	11,500
Formation of ferric sulphate	11,400

The text-books contain very few examples of the analyses of commercial nickel, matte, &c. The Table I., above, is therefore added, which will serve to indicate the general character of the substances that the nickel analyst is called upon to examine nowadays.—W. S.

A New Colour-Standard for Natural Waters. A. Hazen. Amer. Chem. Jour. 14, 300—310.

THE colour of water has been measured by comparing it with the colour produced, by Nesslerising water containing a measured quantity of ammonia. This is open to the objections, that the numbers expressing the colours are not directly proportioned to the colours themselves, and that it is not applicable to very slightly coloured water.

The author suggests in place of this a platinum colour standard which is defined as follows:—"The colour of a water is the amount of platinum in parts per ten thousand, which in acid solution, with so much cobalt as will match the tint, produces an equal colour in distilled water."

To prepare a standard having the value five on this scale, 1.246 grms. potassium-platinum chloride (containing 0.5

grms. platinum), and 1 gm. cobalt-chloride is dissolved in water; 100 cc. concentrated hydrochloric acid added, and the solution made up to 1 litre. Standards for use are made by diluting 1, 2, 3 cc., &c. of this solution to 50 cc. in Nessler tubes, giving colours 0.1, 0.2, &c.; in closed tubes these standards will keep unaltered for a long time.

If the colours do not exactly match the waters, more or less cobalt may be added. With waters of low colour longer tubes may be used. The numbers obtained by this method are practically identical with those obtained by the Nesslerised ammonia standard for colours 1 to 2, but the platinum standard gives numbers proportional to the colours, and may be used for all waters.—A. L. S.

The Estimation of Manganese in Spiegel Iron and Ferro-manganese. M. C. Bastin. *Moon. Scient.* September 1892, 639.

FROM 0.25 to 1 gm. of the material is dissolved in a flask of about 150 cc. capacity, by 50 cc. nitric acid sp. gr. 1.20; 8—10 grms. potassium chlorate are added and the solution boiled for 15 minutes. It is diluted, filtered, and 100 cc. of a solution added containing 6.300 grms. oxalic acid per litre, and 25 cc. sulphuric acid. The mixture is warmed to 80° C. for 10 minutes made up to 1 litre, and the excess of oxalic acid titrated with potassium permanganate solution. One equivalent of oxalic acid decomposes one equivalent of manganese, or $\text{Mn} = \text{oxalic acid decomposed} \times \frac{27.5}{68} = \text{oxalic acid} \times 0.4365$. The permanganate solution is made by dissolving six grms. of permanganate in one litre water. The results yielded are very fairly accurate.—A. L. S.

The Estimation of the Intensity of Colour of Beers and Malt Extracts. C. J. Lintner. *Zeits. ges. Brauw.* 1892, 15, 213; *Chem. Zeit. Rep.* 1892, 16, 234—235.

THE author finds it impossible to prepare a single standard solution for colorimetric purposes, owing to the different tints which occur in beers made from kiln-dried and the so-called patent malt, and in those made from ordinary black malt, a yellow tint occurring in the former and a red one in the latter. Iron-ammonia alum is the only substance which complies with both requirements; the addition of sulphuric acid to the aqueous solution giving the yellow tint and the addition of acetic acid the red one. The author describes and figures a simple "Dilution colorimeter," in which the depth of colour of the liquid under experiment is compared with that of the standard. If they are exactly equal, the number 1 is assigned to the liquid as its colour intensity. The apparatus consists of two equal rectangular glass vessels having parallel sides, and fitting side by side into a case of black enamelled tin, which is furnished with two longitudinal slits in the front and in the back which are covered with milk glass. When in use the apparatus is placed against a window, and the depths of colour of the liquids placed in the two vessels are compared with the eye on looking through the slits.

Method of Use: 1. *Beer*.—The standard solution is prepared by dissolving four grms. iron-ammonia alum in 100 cc. distilled water, with the addition of 2 cc. normal sulphuric acid. 5 to 20 cc. of the beer, according to its colour, are placed in one vessel, and water added from a burette until the intensity of colour equals that of the standard solution which is placed in the other vessel. The intensity of colour, F, then $= \frac{a+b}{a}$, where a is the volume of beer used, and b that of the water added.

2. *Malt*.—(a). Kiln-dried malt. 50 grms. of malt are mashed in the usual manner with 200 cc. water, made up to 265 cc. and filtered, and the colour of the wort compared with the above standard solution. (b). Patent colour-malt. 5 to 25 grms. of the malt, according to its colour, are finely ground, boiled with 400 cc. water for ten minutes, cooled, made up to 500 cc. and filtered. The colouring power of the malt is reckoned as 1, when the colour-intensity of the

extract of 100 grms. of malt in 500 cc. water is equal to 1 as calculated above.

3. *Ordinary Black Malt*.—The standard solution in this case consists of 1 gm. iron-ammonia alum in 100 cc. water, with the addition of 7 cc. of 32 per cent. acetic acid. 2.5 grms. of the finely-ground malt are digested with 400 cc. water for ten minutes, cooled, made up to 500 cc. and filtered. The colouring power of the malt is calculated as in the preceding case.—J. G. W.

ORGANIC CHEMISTRY.—QUALITATIVE.

Identification of Xylose and Distinction from Arabinose.
G. Bertrand. Bull. Soc. Chim. 7—8, 1892, 499—502.

SINCE xylose occupies an important position in the vegetable kingdom, being always found amongst the products of hydrolysis of the incrusting substances of the angiosperms, it is necessary to have some means of identifying it; the author gives a summary of the properties and reactions of xylose, most of which have, however, been described by other chemists.

One hundred parts of water at 20.3° dissolve 117.05 parts of xylose; or, in other words, 100 cc. of a saturated aqueous solution of xylose at 20.3° contain 64.2 grms. of the sugar. Xylose seems to be insoluble in absolute alcohol, but 10 cc. of 90 per cent. alcohol, saturated at 19°, contain 0.329 gm. of the sugar.

The specific rotatory power of xylose is $[\alpha]_D = 20.2$ to 21° according to Koch, $[\alpha]_D = 18.6$ to 19.6° according to Wheeler and Tollens; the author's determinations give $[\alpha]_D = 19.4^\circ$.

Xylose does not ferment with yeast; its reducing power for Fehling's solution is 109.6, when that of dextrose is taken as 100.

A characteristic reaction of xylose, and one by means of which it can be distinguished from arabinose, is the following:—A little xylose is treated with 30—50 times its weight of saturated bromine water, and after keeping for 24 hours the solution is boiled to expel the excess of bromine; after adding excess of cadmium carbonate the solution is filtered, evaporated to a small volume, and mixed with an equal volume of alcohol, when xylobromide of cadmium—

is gradually deposited in crystals; this compound is almost insoluble in dilute alcohol, but much more readily in water, and has no sharp melting point.

Both xylose and arabinose give, as is well known, a violet blue coloration when warmed with hydrochloric acid and a trace of orcinol; the hexoses, on the other hand, give a reddish-orange coloration.—F. S. K.

ORGANIC CHEMISTRY.—QUANTITATIVE.

The Determination of Glycerol in Sweet Wines. M. T. Lecco. Ber. 25, 2074—2075.

By using a large amount of lime, the method of estimating glycerol in wines described by the author (Chem. Zeit. 16, 1892, 504; this Journal 1892, 550) may be applied to sweet wines.

The following method may also be used:—10 cc. wine is mixed with 1 gm. dry powdered calcium hydrate, 10 grms. quartz sand added, and the whole evaporated to dryness on the water-bath. The residue is extracted 4 or 5 times with 96 per cent. alcohol, and the alcoholic solution filtered into a 100 cc. flask. The solution is evaporated on the water-bath and the residue dissolved in 5 cc. absolute alcohol and 7.5 to 10 cc. ether added. When the solution has become clean, it is decanted off, filtered, evaporated, and dried one hour in the water-oven and weighed.—A. L. S.

On the Estimation of Glycerin in Fermented Beverages.
B. Proskauer. Pharm. Central-H. N.F., 1892, 13, 369;
Chem. Zeit. Rep. 1892, 16, 228.

GOOD results are given by the following method;—100 cc. of wine are evaporated to 30 cc., mixed with a few drops of sulphuric acid and 6 cc. of phosphotungstic acid (50 per cent.). The precipitate is filtered off and washed, the filtrate evaporated down on a water-bath with the addition of dry calcium hydrate, and of quartz-sand. The mass in the evaporating dish is then powdered and introduced into a Soxhlet's apparatus. After extracting well with 96 per cent. alcohol, the extract is evaporated in a flask to a syrupy consistence, 25 cc. alcoholic ether (2:3) added, the whole shaken vigorously and allowed to settle. The clear liquid is poured into a long-necked 50 cc. flask, washed with 10 cc. alcoholic ether, evaporated, and dried in a water oven.

—J. G. W.

The Estimation of Invert Sugar by Soldain's Solution.
Striegler. Zeits. Rübenzuckerind. 1892, 42, 457; Chem. Zeit. Rep. 1892, 16, 227.

SOME difficulty is experienced in the removal of calcium salts from syrups and molasses prior to the estimation of the invert sugar in them, potassium and sodium bicarbonates when used alone for this purpose presenting certain objections. The author recommends the use of a solution of sodium oxalate and bicarbonate prepared by dissolving 25 grms. oxalic acid in the smallest possible quantity of water, adding sodium carbonate until a heavy precipitate of sodium bicarbonate falls out, and making up to 500 cc. An excess of this reagent has no prejudicial action and in using it, it is only necessary to heat just to the boiling point.

The author also recommends the preliminary clarification of molasses with blood charcoal as otherwise a too great reduction of copper is obtained, due to matter which is not invert sugar, and which is removed by treatment with

charcoal. The use of lead acetate is, however, objected to, on the ground of its giving a precipitate with the invert sugar itself.

The following is his complete process:—Dissolve 20 grms. of the substance in 140–150 cc. water, add 10–30 cc. of the calcium precipitating solution, heat to boiling and allow to boil up a few times, cool, make up to 200 cc., shake up with blood charcoal, filter and treat 50 cc. with 100 cc. Soldani's solution, which is best prepared by dissolving 150 grms. KHCO_3 and 101.4 grms. K_2CO_3 in 600 cc. water at 50°C ., adding 100 cc. of a solution of 34.639 grms. CuSO_4 in 500 cc. water and making up to a litre.—J. G. W.

The Hops of the Year 1891. M. Levy. Chem. Zeit. 16, 1892, 839.

See under XVII., page 1019.

PATENT.

Improvement in Detection of Foreign Fats in Butter. W. Johnstone, London. Eng. Pat. 20,956, December 1, 1891.

THE invention is based on the fact, discovered by the patentee, that genuine butter does not contain triolein and tributyrin, but a peculiar fat called oleo-vaccio-butyrate of glycerin. The ratio between the liberated oleic and butyric acids is therefore constant, and any excess of the first is proof-positive of an admixture of animal fat, whilst an excess of the latter shows adulteration with a vegetable oil.

The inventor thus describes the actual process:—First, the amount of butyric acid is estimated by any suitable means and calculated to oleo-vaccio-butyrate of glycerin by multiplying by $\frac{650}{88}$. Second, the iodine absorption of the butter, or of its fatty acids, is ascertained by any suitable means, and this is also calculated to the said glycerin compound by multiplying first by $\frac{10}{9}$ and then by $\frac{650}{282}$. If the two estimations agree the butter is pure; if not there has been adulteration. The inventor claims great delicacy for his process, from three to five per cent. of foreign fat being readily detected.—L. de K.

ANALYTICAL AND SCIENTIFIC NOTES.

Slow Combustion of Gaseous Mixtures. P. Askenasy and V. Meyer. Annalen, 269, 49–72.

IN a paper published a short time ago (this Journal, 1891, 752), Krause and Meyer described experiments, the object of which was to try and determine the rate at which combination takes place between oxygen and hydrogen. In the present communication further experiments of the same kind are described, additional precautions having been taken to ensure the purity of the electrolytic gas. In order to try and obviate the influence of the glass surface, to which the irregularities in the earlier results were assigned, various devices were adopted; in some cases the glass bulbs were etched on the inside, in others the electrolytic gas was passed for many hours through the bulbs heated to 518°C . in order to try and obtain an unchangeable surface; experiments were also made with bulbs which had been protected from the light.

These attempts to eliminate the action of the glass surface were, however, entirely unsuccessful, the irregular character of the results being just as pronounced as in the earlier experiments. The effect of coating the inner surfaces of the bulbs with silver was then investigated; although when such bulbs are used combination takes place at a much lower temperature than in the case of the unsilvered vessels the same irregularities are observed, and it is impossible to establish any relationship between the duration of the heating and the quantity of water formed.

The conclusion to be drawn from these experiments is that, even when every imaginable precaution is taken to ensure equality of conditions, it is impossible to determine the relation between the amount of water produced from electrolytic gas and the duration of the heating; the cause of this is doubtless to be sought for in the action of the surface of the containing vessels.

Further experiments will be undertaken in order to try and arrive at a solution of this problem; in the first place the authors intend to modify their method of procedure by employing capillary tubes or silver vessels instead of the glass bulbs, and also to try the effect of heating the electrolytic gas under pressure.—F. S. K.

Photo-Chemical Notes. P. Askenasy and V. Meyer. Annalen, 269, 72–73.

WHEN pure, dry electrolytic gas is exposed to direct sunlight from May to October in sealed glass bulbs, it undergoes no change, as is proved by the fact that on opening the bulbs under water the original volume of the gas is found to have undergone no diminution. Even when moist electrolytic gas is exposed to the concentrated light of a July sun, and at the same time heated to 606°C ., no explosion occurs.

When chlorine and hydrogen are separately exposed to bright sunlight for 3 to 4 hours and then immediately mixed in the dark they do not combine; this experiment proves that Draper's statement to the contrary is untrue, and confirms the results obtained by Bunsen and Roscoe.—F. S. K.

The Resins of Ficus rubiginosa and F. Macrophylla. E. H. Rennie and G. Goyder, jun. Proc. Chem. Soc. 1892, 115, 146.

AN account is given of the results of an examination of the resin of *F. rubiginosa* by De la Rue and Müller, contained in a paper published in the Phil. Trans. of 1860, and the somewhat different results of the authors are then recorded. They have separated a crystalline substance from both resins externally closely resembling De la Rue and Müller's product, but giving numbers for carbon about 3 per cent., and for hydrogen about 1 per cent. higher; the numbers are most in accordance with the formula $\text{C}_{31}\text{H}_{54}\text{O}_2$. This substance is resolved by alkaline hydrolysis into acetic acid and a crystalline substance melting at 114° , of the formula $\text{C}_{32}\text{H}_{54}\text{O}$, very closely resembling the substance described by De la Rue and Müller, which they obtained in a similar way.—W. S.

New Books.

THE JEWELLER'S ASSISTANT IN THE ART OF WORKING IN GOLD. A practical Treatise for Masters and Workmen, compiled from the experience of thirty years' workshop practice. By GEORGE E. GEE. London: Crosby, Lockwood, & Son, 7, Stationers' Hall Court, Ludgate Hill, 1892. 7s. 6d.

THIS is an 8vo. volume bound in cloth, with Preface, Table of Contents, Subject-matter containing 228 pages, and Alphabetical Index. The book is divided into 17 chapters; I. The Chemical and Physical properties of Gold, deals shortly with Fine Gold, Action of Fluxes on Gold, Dissolving Gold, Testing Gold in solution, Granulating and parting alloyed Gold, Various Gold precipitants, Zinc and waste gold solutions. II. The Precipitation of Gold in waste

solutions. III. The Different Colours of Gold. IV. The Mixing and Melting of Gold. V. The Dry-Colouring of Gold. VI. The Wet-Colouring of Gold. VII. The Melting and Casting of Gold. VIII. Electro-Gilding. IX. Some other Modes of Gilding. X. Practical Manipulations, such as gilding plain surfaces, Frosting, metal work, &c. XI. Mixing Alloys. XII. Useful Imitation Alloys. XIII. Hints and Helps, Instructions upon Hall-marking, Gold-testing Needles, Gold Lacquer, Soldering fluid free from Acid, Gold and Silver Solders, Polishing Powder, Gilding Steel, Aluminium Silver, Gilders' Wax, &c. XIV. Collecting and Refining Scrap Gold, Lemel, Wet and Dry Processes for the Recovery of Gold, &c. XV. Sundry Gold Alloys. XVI. Choice Recipes. XVII. Gold Values and Alloys, giving tables of the relative Values of the different Carats of Fine Gold, the Proportions of Alloy and Fine Gold to make any Quality, &c.

A HANDY BOOK FOR BREWERS, BEING A PRACTICAL GUIDE TO THE ART OF BREWING AND MALTING. Embracing the Conclusions of Modern Research which bear upon the Practice of Brewing. By HERBERT EDWARDS WRIGHT, M.A. London: Crosby, Lockwood, and Co., 7, Stationers' Hall Court, Ludgate Hill, 1892. 12s. 6d.

Octavo volume bound in cloth, containing Preface, Table of Contents, text covering 563 pages, Alphabetical Index, and, just preceding it, a Synoptic Table of the various Processes in Malting and Brewing. The work is illustrated by a few engravings, and is subdivided into chapters devoted to the consideration of the following branches of the whole subject:—I. Introductory, Chemical Changes and Preliminary Processes. II. Barley, Malting, and Malt. III. Water for Brewing. IV. Hops and Sugars. V. The Brewing Room. VI. Chemistry as applied to Brewing. VII. The Laboratory, its requirements, and the methods. VIII. Mashing, Sparging, and Boiling. IX. Ferments in General. X. Fermentation with Commercial Yeast, its Science and Practice. XI. Culture from a Single Cell; Wild Yeasts. XII. Treatment of Beer. XIII. The Brewery and Plant. In the first part of the Appendix is given a list of the hop-growing parishes of Kent.

FARMYARD MANURE; ITS NATURE, COMPOSITION, AND TREATMENT. By C. M. AIKMAN, M.A., B.Sc., Lecturer on Agricultural Chemistry, West of Scotland Technical College, &c. William Blackwood and Sons, Edinburgh and London, 1892. 1s. 6d.

SMALL 8vo. volume, with Preface, Table of Contents, and 65 pages of subject-matter. The treatise opens with a brief introduction in a couple of pages, treating of—i. What Fertility of Soil depends on; and ii. The Function of Manures. FARMYARD MANURES.—Solid excreta and urine. Litter. Horse Manure. Cow Manure. Pig Manure. Sheep Manure. Methods of Calculating Amount of Manure produced on the Farm. Fermentation of Farmyard Manure. Conditions influencing Fermentation. Products of Fermentation. Analysis of Farmyard Manure. Comparison of Fresh and Rotten Manure. Methods of Application of Farmyard Manure to the Field. Value and Functions of Farmyard Manure. Appendix, relating to a variety of analyses and experimental trials.

CHEMISTRY OF THE ORGANIC DYE-STUFFS. By R. NIETZKI, Ph.D., Professor of the University of Basel. Translated, with additions, by A. Collin, Ph.D., and W. Richardson. London: Gurney & Jackson, 1, Paternoster Row, 1892. 15s.

This work is the English translation of the well-known German work of Nietzki, and consists of an octavo volume bound in cloth, and containing Author's preface, Translators'

Preface, Table of Contents, Introduction, and text occupying 271 pages. This is followed by a most useful and well-arranged Table of References on the different classes of Dyestuffs, covering 15½ pages, an Appendix containing information concerning the most recent colours, and Alphabetical Index.

The matter is classified as follows:—I. Colour. Chromophors, Chromogens, &c. II. Nitro-compounds. Azo-dyestuffs. Amido-azo-compounds. Oxy-azo-compounds. Azo-dyes from Diazo carbonic acids. Azo-dyes from carbonic acids and diazo compounds. Tetrazo- or Diazo dyes. III. Oxyquinones and Quinone-oximes. IV. Ketone imides and Hydrazides. V. Triphenylmethane Dyes. VI. Quinone-imide Dyes. VII. Azine Dyes. VIII. Aniline Black. IX. Indulines and Nigrosines. X. Quinoline and Acridine Dyes. XI. Indigo Dyes. XII. Euxanthic Acid and Galloflavine. XIII. Canarine. XIV. Murexide. XV. Dyes of Unknown Constitution.

CHEMICAL LECTURE EXPERIMENTS. NON-METALLIC ELEMENTS. By G. S. NEWTH, F.I.C., Chemical Lecture Demonstrator in the Royal College of Science, South Kensington. London and New York: Longmans, Green, & Co., 15, East 16th Street, 1892. 10s. 6d.

This work, as the Preface announces, is designed, firstly, to supply chemical lecturers and teachers with a useful repertoire of experiments, which may be undertaken on the lines laid down with confidence, as resting upon a foundation of solid experience; and secondly, to furnish the chemical student with a book to serve as a companion to the lectures he may attend. The volume is octavo in size, and though the concise table of contents following the preface might have served, yet an alphabetical index at the end forms an additional guide to all details of experiment. The text of the subject proper covers 276 pages. Then follows an article on lantern illustrations, and this is succeeded by an Appendix with useful tables for experimenters, which might be admirably reproduced and embodied in wall diagrams.

The work is illustrated by 224 well-executed woodcuts. Technologists may find specially interesting the experimental treatment of the following subjects:—Ammonia, Oxides of Nitrogen, Diffusion, Combustion, Phosphorus, Sulphur, Sulphur dioxide, Dissociation and Liquefaction of Gases.

MANUAL OF QUALITATIVE BLOW-PIPE ANALYSIS AND DETERMINATIVE MINERALOGY. By F. M. ENLICH, S.N.D., Mining Engineer and Metallurgist, late Mineralogist Smithsonian Institution, and United States Geological and Geographical Survey of the Territories. The Scientific Publishing Co., 27, Park Place, New York, 1892. 18s. (4.00 dollars).

This large and complete treatise is dedicated to Professor Theodor Richter, of Freiberg i.S., the former teacher of the author. It is as a book, large 8vo. in size, and contains Preface, Table of Contents, List of Illustrations, numbering some 26, List of Abbreviations, Introduction, Text, filling 436 pages, and a copious Alphabetical Index. A noteworthy sentence in the Introduction, referring to such matter as fills the pages of this volume, is this:—"No amount of memorising will impress the various reactions upon the student's mind in such a way that he will always recognise them when he sees them." "Practice alone can do this."

Pages 13—32 are devoted to an account of the Appliances and Reagents required for quantitative blow-pipe analysis. This includes a description of "Blast and Flames," pages 26—32. CHAPTER II. deals with the Methods of Qualitative Blow-pipe Analysis. i. Examination of Minerals without the application of heat or reagents. ii. Examination of Minerals with the Application of heat only. iii. Examination of Minerals with the blow-pipe with

Borax and Salt of Phosphorus. IV. Treatment with substances with Soda before the blow-pipe. V. Treatment of Minerals with Soda and Borax before the Blow-pipe, with Nitre, with Potassium Bisulphate, with Potassium Iodide and Sulphur, with Cobalt Solution, &c. Spectrum Analysis. CHAPTER III. Tables giving Reactions for the Oxides of the Earths and Metals. CHAPTER IV. Prominent Blow-pipe Reactions for the Elements and their Principal Mineral Compounds. CHAPTER V. Systematic Qualitative Determination of Compounds. CHAPTER VI. Determinative Tables and their Application. This latter portion of the work furnishes a complete and systematic method of determining minerals by means of blow-pipe and other dry, as well as so-called wet processes of qualitative mineralogical analysis.

PRINTERS' COLOURS, OILS, AND VARNISHES: a Practical Manual. By GEORGE H. HURST, F.C.S., Member of the Society of Chemical Industry; Lecturer on the Technology of Printers' Colours, Oils, and Varnishes at the Municipal Technical School, Manchester. London: Chas. Griffin & Co., Limited, Exeter Street, Strand, 1892. 12s. 6d.

THE writer states in his preface, "The information given as to the properties and preparation of pigments is either based on my own experience or drawn from the most trustworthy sources." His chapter on "Varnishes" has been revised by a personal friend practically engaged in their manufacture. The book is thus not a mere complement from other works. It is of 8vo. size, is handsomely bound in red cloth, and contains Preface, Table of Contents, and subject-matter filling 450 pages. An Alphabetical Index concludes the work. The text is embellished by some 67 wood engravings and contains various useful tables. The work is sub-divided as follows into chapters treating of the subjects of this industry:—

Introductory on Colour and Colour Theories. II. White Pigments. III. Red Pigments. IV. Yellow and Orange Pigments. V. Green Pigments. VI. Blue Pigments. VII. Brown Pigments. VIII. Black Pigments. IX. Lakes. X. Assay and Analysis of Pigments. XI. Colour and Paint Machinery. XII. Paint Vehicles. XIII. Driers. XIV. Varnishes.

DESTRUCTIVE DISTILLATION. A Manualette of the Paraffin, Coal Tar, Rosin Oil, Petroleum, and Kindred Industries. By EDMUND J. MILLS, D.Sc., F.R.S. 4th Edition. London: Gurney and Jackson, 1, Paternoster Row, 1892. 5s.

THIS 8vo. volume is bound in strong waterproof cloth, and so can be used safely on the laboratory table. The contents are the substance of a course of lectures delivered in Anderson's College, in 1875—6, but enlarged upon since that date. The subject-matter covers 183 pages. Then follows a diagram showing the various forms of shale retorts used since the old vertical type largely employed by Young's Paraffin Company, up to types used in 1889 (Stanrigg's), with an explanatory Appendix. Appendix B. comprises a Bibliography on Destructive Distillation, and the book concludes with an Alphabetical Index. The work is well illustrated with tables.

Trade Report.

EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

FERTILISERS IN THE WEST INDIES.

Jamaica.

The American Vice-Consul reports that there was imported into Jamaica during the year ended March 31st, 1891, fertilisers to the value of 2,758*l.*, of which 2,375*l.* in value came from the United Kingdom, 81*l.* from the United States; while for the year ended March 31st, 1892, the total importations amounted to 3,918*l.*, distributed as follows: From the United Kingdom, 3,905*l.*; from the United States, 49*l.*; and the remainder from the West Indies.

It will be seen from this, says the Consul, that although the use of imported American fertilisers is exceedingly small, it is on the increase.

The explanation of the practical monopoly of the United Kingdom in this trade is explained by the fact that the English manufacturers of commercial fertilisers hold themselves in readiness to analyse samples of the soil, in order to arrive at the chemical deficiencies thereof, and then compound the fertilisers to meet such deficiencies. Intelligent and practical users of fertilisers assure him that if American manufacturers will hold out the same inducements in regard to analysing the soils and manipulating the manure to supply the requirements thereof, and in addition thereto will sell at the same price fertilisers of the same commercial value, the item of freights being so much in favour of the United States, her manufacturers can turn the tide in their favour.

Although the area of Jamaica is only 4,193 square miles, it contains a great diversity of soils, and it would therefore require the honest and intelligent preparation of fertilisers on the part of American manufacturers to obtain and hold this trade. And he remarks that the principal crops (cane and bananas) being very exhaustive to the soil, it is a well recognised fact that in a few years at most fertilising must be largely resorted to, as the lands are virtually worn out, and the system of the past in turning out old lands and taking in new can be no longer resorted to, as the lands have all been under cultivation, that is, the kind adapted to the crops named, which as before stated, constitute the principal cultivated crops.

He has been unable to ascertain the chemical value of the fertilisers imported, the quantity, or their selling price.

Martinique.

There is annually imported 20,000 to 25,000 tons of nitrates, phosphates, and ammonia. About one half is in a prepared state, the rest in crude form, which is mixed here by a firm engaged in that business with a capital of 320,000 francs. The firm is entitled *Compagnie des Engrais de la Martinique*. The factory is in the city of St. Pierre.

The material is all imported from the United Kingdom, and is packed in strong bags or barrels. The finished product is used for sugar cane only. Its analysis is as follows:—

Cross's Special Cane Fertiliser.—Nitrogen, equal to 9 per cent. of non-volatile ammonia, 19 to 20 per cent. of soluble phosphates, and 3 to 5 per cent. of insoluble phosphates, besides 3 to 4 per cent. of soluble salts of potash and alkaline salts.

Cross's Early Potassic Cane Fertiliser.—Nitrogen in various forms equal to 6½ per cent. of ammonia; phosphoric acid, soluble equal to 15 to 16 per cent. of phosphate rendered soluble; phosphoric acid, soluble, in finely prepared form, equal to 5 per cent. of phosphate of lime; potash equal to 10 per cent. of sulphate of potash.

There are no duties on fertilisers, and wharfage is nominal. Small lots of sulphate of ammonia and nitrate of potash have been recently imported from the United States through a commission house.

The price laid down at Martinique is about 230 to 235 francs per ton of 2,240 lb. for Cross's and other English manufacturers' fertilisers.

The quantity used per acre varies. The soil in the uplands being loose and rains frequent, 250 lb. to the acre is used; the lowland being more compact and clayey, 200 lb. to the acre is all that is required. If subsoiling was more practised by planters, a less quantity would be necessary.

The terms on which the business is carried on are as follows:—Drafts of Colonial Bank of London agency at Martinique of New York or London at 5·25 francs to the dollar on delivery.

It would appear that, with cheap material in the United States and the short distance to transport the finished article, the United States should command the market, as they do for yellow pine lumber, flour, corn, lard, and meat products.

St. Thomas.

There is no demand for fertilisers.

The consular agent at Santa Cruz reports that—

Many years ago there were some guano and patent fertilisers imported from England; but of late years, owing to the low price of sugar, the planter has been satisfied if he could provide sufficient manure.

This island is non-productive, and very little cultivation is carried on in the island of St. John; but there may be a field for trade in fertilisers in the island of Santa Cruz if a proper canvass be made by dealers.

St. Christopher.

The greater part of the commercial fertilisers used on this island are imported from Great Britain for various reasons. The two strongest reasons are the following: First, nearly all the landowners reside in Great Britain and are largely controlled by home influence; second, a few years ago the English fertiliser companies sent out a chemist who analysed the soil and prepared a special formula of a fertiliser for the sugar-cane plant, which is very popular here and sells at the highest price, 12*l.* per ton.

In referring to prices, the showing is largely in favour of the United States; and the freights from New York to St. Christopher are only one-half of what they are from London. Now, with a little enterprise and industry on the part of fertiliser manufacturing companies in the United States, they could very soon have all this trade. They must not forget that the island of St. Christopher is apparently one sugar-cane farm. The different estates are not divided by any fences, simply turning rows and ditches.

Having travelled all around the island several times it seems to be nothing but sugar-cane plantations, all well cultivated.

The farms require a good sugar-cane fertiliser, and if our manufacturers will send down a chemist, analyse the soil, and prepare as good a fertiliser as the special fertiliser imported from London, they will control this trade, as the freights from New York, as heretofore stated, are only one-half what they are from London.

The freights should be very cheap from Savannah and Key West, as it is only 800 miles from the former and 600 miles from the latter place to this island.

The United States should establish a weekly mail from Key West to these islands. We are here over 600 miles from America, and cannot get a regular mail, owing to the employment of the Quebec line of Canadian vessels hailing from London, which is all the time fighting for freights and is perfectly indifferent about the United States mails. At times (twice) we have had two mails within 48 hours, at other times not a mail in a month.

Trinidad.

Pursuant to instructions contained in Department Circular, dated June 2, 1892, calling for a report upon the trade in commercial fertilisers in this consular district, it has been observed in respect to the three islands constituting the district, that the only substantial opening for American trade in fertilisers is in the island of Trinidad. The industry of Grenada is principally limited to cacao, and the sugar industry in both Grenada and Tobago is comparatively of not much importance.

Trinidad, however, imported in 1890 fertilisers (or manures, as is the Custom house designation) to the value of 40,892*l.* The importations last year (1891) were considerably less, being valued at 19,867*l.*

The value of importation for 1890 and 1891 was as follows:—

From	1890.	1891.
	£	£
United Kingdom	40,682	19,135
British West Indies.....	5	—
British Guiana.....	200	8
United States.....	5	558
France	—	166
Total	40,892	19,867

While it will be seen that the United States got somewhat of a foothold last year, it is still not fairly in the market. Within the last few months several American manufacturers of fertilisers have made inquiries of this consulate and have otherwise indicated a disposition to extend their trade to Trinidad, and it is reasonable to expect that, within a few years, the above figures will undergo a great change in favour of the United States.

The only crop of Trinidad worthy of consideration in this connection is the sugar-cane crop. Imported manure might be of service in promoting the growth of cacao trees and cocoa-nut trees; it has not transpired that any has been used for that purpose, except in the way of experimenting however.

About seven-eighths of the sugar-cane crop belongs to residents of the United Kingdom, who obtain their fertilisers through their own agents.

The largest local planter uses principally a mixture of his own, composed of two-thirds ground phosphate and one-third ammonia. Both ingredients are imported in casks. The first cost, net, of ammonia in London is, say, about 10*l.*, and delivered on wharf in Port of Spain (Trinidad), say, 12*l.*, including freight, casks, lighterage, and all other expenses. The ammonia is guaranteed to be 24½ per cent., which is understood here to be about as pure as is ever manufactured for fertilising purposes. The ground phosphate costs, net, in London about 1*l.* 18*s.* 2*d.*, and delivered here on wharf, including all expenses and charges, say 3*l.* 14*s.*

There are no tonnage or lighthouse dues at this port, and all manures are entered free of duty.

Bahamas.

There is no importation of fertilisers into this colony from Europe. A considerable quantity of guano or cave earth—a rich bat deposit found in caves on the out islands—exists in this colony. Prior to 1885 from 2,400*l.* to 3,000*l.* worth of this deposit was exported annually, most of it going to the United States to be mixed with other fertilisers. Since 185 the policy of the colonial government being opposed to the removal of any fertilisers from the islands, exportations of this guano have been prohibited by law, with a view to encourage its use by local agriculturists. It is not, however, much used, being, perhaps, too rich in its natural state.

Within the last three or four years, however, a demand has arisen for fertilisers in the cultivation of pine apples, and foreign fertilisers have been introduced with excellent results, the fruit being larger and of better flavour, and old, worn fields developing new life and vigour.

These fertilisers come entirely from the United States, and the trade is rapidly increasing. In 1891 fertilisers to the amount of 2,175 barrels, worth about 2,400*l.*, were imported from the United States and used during the year. There will probably be a decided increase in the amount imported in 1892.

There is no reason to anticipate that manufacturers of fertilisers will meet with any European competition here.

U.S. Consular Reports.

CHINESE IMPORTS OF GLASSWARE.

The German Consul at Chefoo writes that, although the manufacture of glass may have been known in China for centuries, it is far from having arrived at a state of perfection. Chinese glass is thin, defective, and not wholly transparent; window glasses are also imported from abroad. Decanters, bottles for wine and beer, also find a market, and are sold to the natives at very good prices.

ADULTERATION IN AGRICULTURE.

The Board of Agriculture, in March last, appointed a Departmental Committee to inquire into and to report upon the representations made by Chambers of Agriculture, and other bodies or persons, with reference to the adulteration of artificial manures and fertilisers and feeding stuffs used in agriculture. The committee consisted of Mr. J. S. Gathorne Hardy, M.P. (Chairman), Sir Jacob Wilson, Dr. James Bell, Mr. J. F. Rotton, Q.C., Mr. F. A. Channing, M.P., Mr. Peter McLagan, M.P., and Mr. Albert Pell. The Committee examined a number of witnesses, whose evidence, together with their own report, was issued yesterday. There is a preponderance of evidence to the effect that a considerable amount of fraudulent dealing (especially in the case of compound manures), exists, and that there is a system of selling unguaranteed and comparatively worthless articles at an excessive price. These frauds are, however, the Committee remark, less practised than formerly, and have a tendency to diminish. But, in view of this state of things, the Committee think that, in the interests of agriculture, some legislation is desirable which shall render it more easy for the purchaser to ascertain the real value of the article he is being supplied with. They recommend—That all home-manufactured artificial manures and fertilisers, both simple and compound, should be sold with a guaranteed analysis in writing stating the percentages of fertilising ingredients; that all imported artificial manures and fertilisers be sold with a copy of the import analysis, and that such import analysis be, within reasonable limits, binding on the seller; that the Board of Agriculture should issue clear and simple instructions for taking samples, and that no sample be taken for analysis except after due notice to the vendor, that he may be present by himself or his agent; that where there is any deficiency in any of the items guaranteed the vendor shall be held liable upon civil proceedings to pay the purchaser, in compensation, the value of the article deficient, setting against it, however, the value of any item which may be in excess of the guarantee; that any deficiency due to fraud be made an offence punishable upon summary conviction by fine or imprisonment; that no criminal prosecution be undertaken unless it is the opinion of an analyst appointed by the Board of Agriculture, or of an analyst authorised by them to act for this purpose, that the case is one for such proceedings to be taken; and that the Board of Agriculture, county councils, agricultural societies, chambers of agriculture, farmers' clubs, co-operative societies, and like bodies be empowered, if they think fit, to institute prosecutions under this clause.

With regard to feeding stuffs, the Committee find that the trade in oil cakes is a field in which the practice of adulteration is particularly prevalent, and that there is a large quantity of articles more or less impure or adulterated

sold as genuine or pure products. They recommended that all simple feeding cakes composed of one substance or the product of one seed, and called after the name of such substance or seed, be required to be sold under the distinctive name of such substance or seed, and be thereby guaranteed "pure and suitable for feeding purposes"; that all other cakes be sold as mixed or compound cakes, or by some designation fixed by the Board of Agriculture; but this should not exclude the use of any trade description or fancy name for such cakes, provided that one of the two words "mixed" or "compound," or some other term to be fixed by the Board of Agriculture, be affixed to such description or fancy name; that the presence of deleterious ingredients in any article sold for feeding stock be prohibited under a penalty; that the addition of any worthless material undeclared in any article sold for feeding stock be treated as an offence subject to a penalty; that any guarantee or analysis voluntarily given be binding on the vendor; and that the same penalties apply in the case of feeding stuffs as of manures.

Mr. Channing makes a supplementary report on feeding stuffs. He explains that he signed the report of the Committee both as regards manures and feeding stuffs, but while agreeing that the recommendations of the report as to feeding stuffs will give some protection to the purchaser, he dissents from certain paragraphs, and is of opinion that the frauds shown to be prevalent in the manufacture and sale of cakes and other feeding stuffs will be most effectually checked by a general system of sale under guaranteed analysis. He makes the following recommendations:—That all feeding cakes and stuffs be sold with a guaranteed analysis giving the percentages of the nutritive elements and the percentages of indigestible fibre, mineral elements (including sand), and moisture; that all simple feeding cakes composed of one substance or the product of one seed, and called after the name of such substance or seed, be sold under the distinctive name of such substance or seed, and guaranteed "pure and suitable for feeding purposes"; that all other cakes or feeding stuffs be sold either as "mixed" or "compound," or under designations to be fixed by order of the Board of Agriculture; that the presence of deleterious ingredients in any article sold for feeding stock be prohibited under a penalty; that the addition of any worthless material undeclared in any article sold for feeding stock, or wilful misrepresentation either as to the designation of any cake or stuff, or as to any of the percentages required to be stated in the guaranteed analysis, be treated as an offence subject to a penalty; that the Board of Agriculture should prescribe from time to time, by order, margins of deviation within which fraud shall not be presumed, and scales of indemnity for deficiencies, and also make regulations from time to time to secure uniformity of sampling and analysis; and that the same penalties apply in the case of feeding stuffs as of manures.

GENERAL TRADE NOTES.

THE PETROLEUM INDUSTRY AT BAKU.

The *Deutsches Handels Archiv* for November states that owing to the over-production of crude naphtha this industry is now passing through a severe crisis at Baku, several firms of producers and refiners having either stopped payment or come to some arrangement with their creditors.

The yield of oil from both old and new naphtha fields has been exceptionally plentiful, notwithstanding the prognostications as to their exhaustion. Quantities of crude naphtha are going to waste owing to the overflowing of the collecting reservoir. Some springs are yielding as much as half a million pounds per day (pound = 36 lb. avoirdupois), and as soon as one becomes exhausted fresh ones are discovered. At Bibi-Abad superfluous naphtha is allowed to flow into the sea.

Twelve months ago a pound of crude naphtha was worth from 8 to 10 copecks from 5*d.* to 5½*d.* per cwt.). The price is now fluctuating between 4 copecks and 1 copeck the pound, and naphtha is said to be even given away.

Apart from the more careful process of refining to which it is subjected, American petroleum (according to the report) is somewhat superior to Russian as regards quality, consequently Americans have been able to keep their prices somewhat in excess of those for Russian oil.

The Baku naphtha industry possesses an advantage over that of North America in consequence of the large proportion of valuable residues contained in Russian oils. Even now the Russian markets can absorb more than 1,600,000 tons of residues, the use of which as fuel is daily becoming more extended in industrial establishments. No profitable commodity are the residues that refined petroleum may be treated as a side product and sold at low prices for lighting purposes.

The average price at Baku of a pound of pure petroleum is 28 copecks. Russian naphtha yields about 33 per cent. of petroleum. Supposing the price of one pound of naphtha to be $2\frac{1}{2}$ copecks, the cost of manufacturing one pound of petroleum would be as follows:—

	Copecks.
3 pounds naphtha at $2\frac{1}{2}$ copecks	7.5
Cost of refining, acids, soda, chemicals.....	3.9
	10.5
Residue of $1\frac{1}{2}$ pounds, now worth about 3 copecks the pound value to be deducted	4.5
Cost of production of 1 pound of petroleum	6.0

When the price of residues is higher (it sometimes exceeds 6 copecks the pound), the cost of production of pure petroleum is still smaller.

America, however, possesses the great advantage of cheap sea freights, whereas the cost of transporting one pound of petroleum from Baku to Batoum is 19 copecks, apart from charges for frequent reloading, and finally sea freight. Meanwhile the proposal for laying down pipes between Baku and Batoum for conveying crude naphtha hardly seems likely to be carried out, although there can be no doubt as to its technical feasibility. Besides, the project of pumping naphtha to Batoum is opposed by the powerful interest of Baku refiners.

THE RUSSIAN OIL INDUSTRY.

The sittings of the eighth Congress of naphtha producers were recently concluded at Baku. Obligatory sorting of illuminating oils according to their degree of refinement, and the alteration of their classification for purposes of taxation, constituted two important subjects of discussion. A majority of the Congress approved of the suggestions of a special committee of members recommending that all illuminating oils sent out from the works at Baku should be tested as to the degree of their transparency, the extent of their purification by sulphuric acid and caustic soda, and the degree to which they become turbid when water is added. The recommendation of the committee as to the retention of the present temporary classification of oils for excise duty was also approved by the Congress.

The improvements of the conditions affecting the export of kerosene to the far East and the reduction of the flashing point of kerosene destined for export abroad, were questions which also engaged the attention of the Congress. In connection with the former it was proposed that pipes should be laid down for the conveyance of kerosene from Enzeli to the Persian Gulf. It is computed that by this means a saving of from 1s. to 1s. 6d. per cwt. would be effected in the delivery of this product in the far East. Russian kerosene would then be secured against competition with America, and a market for about 9,600,000 cwt. per annum obtained. This question has been referred to a committee, which will present its report at the next Congress.

The advocates for a lower flashing point for oils destined for export urged that the present compulsory high flashing point and specific gravity of Russian oils place them at a disadvantage with those of the United States. The proposal was, however, negatived in consequence of the evidence of representatives of the leading firms, who maintained that

the high flashing point which was so distinctive a characteristic of Russian oils, as compared with the dangerous products of America, was essential for ensuring the continued preference to the latter.—*Industries.*

RUSSIAN CHEMICAL MANUFACTURES.

The value of the native manufactures of such articles as oils, soap, lac, matches, alizarine-aniline dyes, white lead, barytes, oxide of zinc, dye extracts, ochre, &c., was 22,300,000 roubles in 1888, and the number of factories engaged in their manufacture was 1,046. The foundation of purely Russian industries has, however, been laid as regards soap, matches, bichromate of potash, and a number of mineral dyes. The new Customs tariff does not merely aim at the protection of Russian raw materials, but is also designed to foster those branches of the chemical industry which furnish the materials required in the primary and final stages of a flourishing industry. The soda factories which obtain soda from salt belong especially to this category, owing to the large quantities of valuable acids and alkalis obtained in the process. There is a great demand for these substances in Russia, especially in glass factories, kerosene refineries, soap-boiling and bleaching establishments.—*Ibid.*

LITHOGRAPHIC STONE DEPOSITS IN THE OURAL MOUNTAINS.

The *Journal de St. Petersburg* for the 15th October states that to the number of mineral riches of the Oural not yet worked are to be added important quarries of lithographic stone, situated in the district of Krasnoufimsk, province of Perm. These deposits have been known for fifteen years, and the lithographic stone which they yield has been recognised as excellent, but until recently nobody has ventured to work the quarries in question. Last winter the quarrying of the lithographic stone was commenced, and according to the *Novoe Vremya* it will be sold in depôts established in St. Petersburg for the purpose.

WRITING PENS MADE OF CELLULOID.

The *Hundels Museum* is responsible for the statement that in France pens for writing are now being made from celluloid, &c., in the following manner:—Thin sheets manufactured from celluloid, chonite, vulcanite, &c., corresponding with the outlines of a pen, are stamped out, punched, and finally laid in a softened condition in a press that has been heated, by which means they receive the desired shape. After being cooled in a water-bath the pens thus obtained are split with a knife.

MINERAL PRODUCTS OF THE UNITED STATES FOR 1891.

The United States Geological Survey, Division of Mining Statistics and Technology, has sent us an advance proof of the next edition of the chart showing the total mineral products of the United States, which will be issued in a short time. The figures for 1891 are here reproduced:—

PRODUCTS.	1891.	
	Quantity.	Value.
Metallic:		Dols.
Pig iron, value at Phil- Long tons	8,279,790	128,337,985
adelphei.

THE SCOTCH OIL TRADE.

The Standard Oil Company has intimated another reduction of $\frac{1}{4}d.$ per lb. in the price of paraffin scale, and producers have been obliged to follow the cut on all their scale products. Scotch hard scale is now no better than $1\frac{1}{4}d.$ to $1\frac{3}{4}d.$ per lb.; some sellers have offered to deal at the former figure without finding buyers. This latest reduction has been mainly brought about by the demoralization which exists in the candle trade by the underhand dealing which is alleged in that connection, and by the difficulty which some importers and some local concerns experience in getting rid of their stock of scale. Running contracts participate in the reduction, which came into force on December 9th. Since the break up of the producers' combination paraffin scale has been lowered $1\frac{1}{2}d.$ per lb., nearly 40 per cent. On the ton of scale that represents a loss of over 10*l.* per ton, and on the Scotch make alone the difference to the trade compared with what would have been the yield for one year had the price been maintained at its old level is between 200,000*l.* and 250,000*l.* Following on the reduction in the price of paraffin scale, the candle-makers have reduced their list prices for white candles by 6*d.* and the yellows by 3*d.*—each per dozen pounds. The reduction in whites is equal to double what has been taken off wax. One of the Scotch companies connected with the associated companies has taken $\frac{1}{4}d.$ per gallon off burning oil, although the demand at present is reported good.—*Chemical Trade Journal.*

BOARD OF TRADE RETURNS.

SUMMARY OF IMPORTS.

	Month ending 30th November

Monthly Patent List.

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

20,541. J. Whyte, H. Whyte, and A. W. Cooper. Improvements in evaporative condensers. November 14.

20,595. F. W. Scott, E. G. Scott, and F. W. Scott, jun. Improvements in or connected with evaporating or concentrating apparatus. November 14.

21,261. E. Hesketh and A. Marec. Improved apparatus for producing cold. November 22.

21,275. J. H. Lewis. Improvements in apparatus for the absorption of chlorine and other gases (applicable also to the washing or scrubbing of gases). November 22.

21,454. J. C. Caivert. Improvements in apparatus for controlling the flow of fluids under pressure. November 24.

21,495. C. Musker, A. Musker, and A. Webster. Improvements in apparatus for evaporating salt water or other liquid. November 25.

21,744. J. Laidlaw. Improvements in centrifugal machines for separating fluids of different densities. November 29.

22,005. J. J. Hicks and G. H. Zeal. Improvements in hydrometers and saccharometers. December 1.

22,157. J. J. Melville. Improvements in or relating to apparatus for treating solid, semi-solid, or liquid substances with gases. December 3.

22,407. D. G. Sinclair and J. V. Dunlop. Improvements in and relating to machinery for the manufacture of fuel briquettes, firebricks, silicious blocks, and the like. December 7.

22,531. W. Deighton. Improvements in and connected with furnaces or kilns using solid or gaseous fuel for burning or calcining limestone, ore, and like substances. December 8.

23,217. J. C. Eno and R. Jackson. Improvements connected with machinery for drying powdered substances particularly applicable for the manufacture of fruit salt. December 16.

23,281. T. Mudd. Improvements in condensers. December 17.

23,287. B. J. B. Mills.—From A. Gilliard, P. Monnet, and J. M. Cartier, France. Improvements in means or receivers for the preservation and application of chloride of ethyl and other volatile liquids, to be employed principally in the production of cold. December 17.

23,297. Sir Lowthian Bell, Bart. Improvements in evaporating brine and other solutions. December 17.

COMPLETE SPECIFICATIONS ACCEPTED.*

1891.

20,413. G. Bamberg. *See* Class XI.

22,639. E. S. Arrighi. Improvements in and in the manufacture of clinical and other thermometers, and in apparatus therefor. December 7.

1892.

541. L. Roumien. Filtering receptacle for substances from which oil or other liquid is to be expressed by hydraulic and other presses. December 14.

836. A. M. Strathern and A. S. Strathern. Apparatus for governing or regulating the pressure or flow of illuminating gas or other fluids. November 23.

845. H. E. Newton.—From R. N. Oakman, jun. Gas furnaces. November 23.

1172. A. T. Rapkin and F. Cossor. Thermometers. November 30.

1181. W. J. Lomax and C. J. Lomax. A combined refuse furnace and gas apparatus. November 30.

1991. J. Wright. Apparatus for heating water and fluids of all kinds; also applicable to ammoniacal and other liquids for distillation for steam boilers or any other purposes. December 14.

2790. J. W. Bowley. Apparatus for producing cold in or freezing liquids. December 21.

19,213. I. Levinstein. *See* Class VII.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

20,709. L. Van Vestrant and M. Graham. Improvements in apparatus for charging inclined gas retorts. November 16.

20,710. L. Van Vestrant. An improved apparatus for charging inclined gas retorts. November 16.

20,769. T. Bauer. Improvements in coke furnaces. Complete Specification. November 16.

20,783. T. F. Eunis and G. F. M. Eunis. Improvements in the manufacture of coal-gas. November 16.

20,860. J. Love. Improvements in apparatus for carburetted or enriching gas or air. November 17.

20,869. V. B. Lewes. Improvements in apparatus for the manufacture or production of gas. November 17.

21,008. J. D. Hall. Improvements in or connected with apparatus for producing illuminating gas. November 19.

21,028. W. S. Sutherland. Improvements in and appertaining to gas producers. November 19.

21,151. W. Henry and J. Henry. An improvement in the manufacture of Irish peat into fuel for steam and household purposes. November 21.

21,444. R. Adcock. An improved smoke consumer for destroying the carbon products of gas combustion and increasing the power of the gas light. November 24.

21,511. J. S. Muir. Improvements in and relating to the manufacture of cyanogen compounds. November 25.

21,647. P. Dvorkovitz. Improvements in apparatus for the manufacture of gas and of by-products from liquid hydrocarbons. November 26.

21,648. P. Dvorkovitz. Improvements in and apparatus for the manufacture of gas and of by-products from liquid hydrocarbons. November 26.

21,649. R. O. Paterson. Improvements in and apparatus for the manufacture of gas for illuminating or other purposes. November 26.

21,871. H. Fourness. Improvements in valves and apparatus employed in the manufacture of illuminating and heating gas. Complete Specification. November 30.

21,914. H. Pazolt. The manufacture of an improved artificial fuel. Complete Specification. November 30.

22,079. S. Y. Shoubridge. Improvements in apparatus for charging gas retorts. December 2.

22,174. H. E. Newton.—From R. N. Oakman, jun., United States. Improvements in gas-producing plant. December 3.

22,767. T. Cross. Improvements in distribution of liquor in ammonia scrubbers or washers. December 12.

22,780. G. Moss. Improvements in means for increasing the illuminating power of lamp flames. December 12.

22,941. W. Willis, E. J. Humphery, and W. H. Smith. Improvements relating to the production and use of light, and to apparatus therefor. December 13.

23,236. H. H. Lake.—From E. Clarenbach, Germany. Improvements relating to the smokeless combustion of fuel and to apparatus for effecting such combustion. December 16.

23,299. A. M. Chambers and T. Smith. An improved process and apparatus for separating fine coal slack from impurities. December 17.

COMPLETE SPECIFICATIONS ACCEPTED.

1892.

864. J. Ruscoe. Apparatus for charging gas retorts. November 30.

964. C. Allina. Solidifying petroleum and the carbohydrates contained in same for facilitating transportation and use as fuel, also reliquefying same. November 23.

1437. I. S. McDougall and J. T. McDougall. Treatment of oils for rendering them capable of transport or storage, and of use as fuel, or as illuminants with greater safety and convenience than hitherto. November 30.

1575. A. Klonne. Manufacture of illuminating and heating gas, and in apparatus therefor. November 30.

1647. J. Mitchell. Coke ovens. December 7.

2073. W. H. Wilson. Manufacture of illuminating gas. December 14.

5620. F. A. Tagliaferro, A. A. Moore, and R. Campion. Manufacture of fire-lighters and artificial fuel. December 7.

8949. T. J. Barnard. Manufacture of fuel, together with the means and combinations in connection therewith. December 14.

9114. R. N. Oakman, jun. Gas-producing plant. November 23.

9854. H. Birkbeck.—From E. B. Muller. Process for manufacturing compact pit coal out of pit coal dust, slack, or small pieces of pit coal. December 7.

14,862. C. R. Poulsen. New or improved apparatus for the production of ozone by means of phosphorus. December 7.

16,750. F. Grein. Charging machine for gas retorts. November 30.

17,484. P. Jensen.—From H. Stiemer and Ziegler. Process of and apparatus for preparing tar, oil, paraffin, pitch, heating and illuminating gases, and large coke from fibrous organic materials such as peat and lignite. December 21.

* *See* Note (*) on previous page.

19,477. R. Campion. The employment of certain ingredients and means for the manufacture of fire-lighters therefrom. December 7.

19,630. H. Galopin. Apparatus for using liquid fuel for lighting and heating purposes. December 21.

19,655. H. G. O'Neill. Improvements in and relating to a method of and means for heating by electricity. December 21.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, ETC.

APPLICATIONS.

21,343. W. J. Wisse and A. Schueller. New or improved treatment of hydrocarbons (or of analogous substances composed mainly of hydrogen and carbon) to decompose them and obtain various products. November 23.

21,809. G. J. Epstein. Improvements in the treatment of pitch or tar and like residues resulting from the manufacture of oils or fats, or wax, or from gas or the like. November 29.

COMPLETE SPECIFICATION ACCEPTED.

1892.

17,484. P. Jensen.—From H. Striener and M. Ziegler. See Class II.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

21,139. H. E. Newton. — From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in and relating to the manufacture and production of diphenyl-naphthylmethane dyes, and of materials therefor. November 21.

21,154. H. H. Lake.—From Wirth and Co., agents for A. Leonhardt and Co., Germany. Improvements in the manufacture of colouring matters. November 21.

21,166. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Application of non-sulphonated azo-colouring matters insoluble in water as body-colours, and in substitution for mineral colours for printing on textile fabrics. November 21.

21,167. O. Imray. — From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Manufacture of blue colouring matters from orthodinitro-anthraquinone. November 21.

21,168. O. Imray. — From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Improvements in the production of blue colouring matters from amido-nitro-anthraquinone. November 21.

21,440. Read, Holliday, and Sons, and K. B. Elbel. Improvements in the manufacture of azo-colouring matters. November 24.

21,968. A. Lembach and C. J. Wolff. Improvements in and connected with the manufacture of oxyquinoline-phenolsulphonic-oxyquinoline and its homologues. Complete Specification. December 1.

22,443. O. Imray. — From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Improvements in the manufacture tetra-nitro-anthrachryson. December 7.

22,572. S. Pitt.—From L. Cassella and Co., Germany. A new group of basic colouring matters, and means for producing the same. December 8.

23,211. H. E. Newton. — From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of new colouring matters. December 16.

23,212. H. E. Newton. — From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of new basic colouring matters. December 16.

23,213. H. E. Newton. — From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of new derivatives of triphenylmethane and diphenyl-naphthylmethane. December 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1892.

802. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik. Manufacture of dyes of the rosaniline series and of leuco-compounds thereof. November 30.

1390. H. H. Lake.—From Wirth and Co., agents for Leonhardt and Co. Manufacture of colouring matters. November 30.

1657. B. Willeox.—From The Farbwerke vormals F. Bayer and Co. Manufacture of colouring matters derived from anthraquinone. December 14.

2408. C. D. Abel.—From The Actiengesellschaft für Anilin Fabrikation. New manufacture of bases and of colouring matters therefrom. December 7.

2617. O. Imray.—From The Farbwerke vormals Meister, Lucius, und Brüning. Manufacture of ethoxyphenylmethyl-pyrazalone and of para-ethoxy 1 phenyl-2,3 dimethyl-5 pyrazalone. December 21.

2789. S. Pitt.—From L. Cassella and Co. Production of azo dyes. December 21.

2953. C. D. Abel.—From The Actiengesellschaft für Anilin Fabrikation. Manufacture of new bases and colouring matters therefrom. December 14.

4109. A. Bang.—From G. A. Dahl. A new black azo dyestuff, and the production of the same. December 14.

V.—TEXTILES, COTTON, WOOL, SILK, ETC.

APPLICATIONS.

20,839. A. Ambler, S. Ambler, and F. Ambler. Improvements in the cleansing, treating, or washing of wool and like animal fibres, and in apparatus employed therein. November 17.

22,736. F. Lehner. Improvements in the process and machinery for producing a thread or filament similar to silk. December 10.

23,156. T. B. Greenwood. See Class VII.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

15,808. A. S. Oetzmann and S. J. Narracott. Manufacture of coverings for floors and other surfaces, and apparatus therefor. November 23.

20,625. W. Bottomley.—From G. E. Armstrong. Apparatus and processes for treating fibrous material. December 21.

22,303. F. Reddaway. Manufacture of oil baizes, American leather, cloth, and other waterproof fabrics. December 14.

1892.

10,834. A. Bayer and K. Herold. A process for freeing sheep's wool from pitch and other impurities. December 14.

19,776. F. Doller and R. Wolfenstein. Process and apparatus for waterproofing woven fabrics. December 7.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

20,553. C. S. Bedford. Improvements in dyeing. November 14.

21,049. C. D. Abel.—From R. Koepf and Co., Germany. Process for fixing mordants on fibre for dyeing. November 19.

21,189. R. B. Archibald. A machine for dyeing wool yarns and similar material. November 22.

21,714. F. W. Hayward, A. S. King, and A. W. Loveland. Improved means and apparatus for surfacing paper or other material with colour, gum, oil, varnish, or the like. November 28.

22,264. A. S. King. Improved means and apparatus for wholly or partially coating or surfacing sheets of paper and other material with colour, gum, oil, varnish, or the like. December 5.

22,293. A. F. St. George. A method of and apparatus for colouring and inlaying coloured designs upon and through floor and wall covering materials. December 6.

23,262. J. Robb and J. Grime. Improvements in and connected with the production of coloured patterns in combination with aniline black on woven fabrics. December 17.

COMPLETE SPECIFICATIONS ACCEPTED.

1892.

282. E. Woodcock, sen., N. O. Woodcock, and E. Woodcock, jun. Improved machine for dyeing, scouring, bleaching, sizing, carbonising, and drying. December 14.

1506. J. Dawson. Method and apparatus for utilising the heat of spent liquors or liquids for dyeing, manufacturing, and other like purposes. December 7.

19,079. F. Schreurs. A new process and apparatus for printing and dyeing fabrics. December 14.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

20,921. F. H. Gossage and J. Williamson. Improvements in the manufacture of sulphide of sodium or of sulphide of potassium from their respective sulphates. November 18.

21,275. J. H. Lewis. See Class I.

21,294. T. D. Owen. Improvements in tanks for containing hydrochloric acid. November 23.

21,298. A. McKenzie. A new or improved soldering flux or acid. November 23.

21,476. C. S. Ellery. Improvements in the manufacture of ammonium sulphate and other salts. November 24.

21,520. The Manchester Oxygen (Brin's Patent) Company, Limited, and W. M. Jackson. Improvements in the manufacture of carbonic acid, lime, magnesia, and other oxides. November 25.

21,702. E. Bouchaud-Praceiq. A process for utilising waste acid sodium sulphate. November 28.

21,723. H. H. Lake.—From L. Sternberg, United States. An improved process of obtaining ammonia and ammonia salts from nitrogenous organic matters. Complete Specification. November 28.

21,735. T. T. Best. Improvements in the manufacture of chlorate of soda. November 29.

21,807. S. Z. de Ferranti and J. H. Noad. Improvements in or appertaining to the manufacture of caustic soda and chlorine. November 29.

21,824. W. C. Sellar. Improvements in the production of cyanides of the alkali metals. November 29.

21,825. W. C. Sellar. Improvements in the production of cyanides of the alkali metals. November 29.

22,078. T. Hughes. The concentration of sulphuric acid. December 2.

22,139. J. Levinstein. Improvements in the manufacture of persalts of iron. December 3.

22,237. H. Cosnett, B. C. Bennison, S. Hayes, and P. Smallwood. New or improved means and apparatus for obtaining chlorine gas from the spent liquors produced in the manufacture of soda ash, and in means and apparatus for the manufacture of chloride of lime therefrom. December 5.

22,238. S. Walker and S. S. Walker. Improvements in the production of carbonic acid. December 5.

22,415. W. Mills. Improvements in the manufacture of soda, and apparatus therefor. December 7.

22,455. C. P. Taylor. Improvements in the manufacture of carbonate of soda, caustic soda, and chlorine, and in apparatus employed in the said manufacture. December 7.

22,523. F. H. Gossage and J. Williamson. An improvement in the manufacture of bicarbonate of soda and soda ash. December 8.

22,602. R. Dempster. Improvements in apparatus for the manufacture of sulphate of ammonia and liquid ammonia. December 9.

22,714. P. Marquart. Improvements in the manufacture of boric acid and borax. December 10.

22,817. E. Rotondi and C. M. Michela. A process for manufacture of acetic acid. Complete Specification. December 12.

22,819. E. Placet and J. Bonnet. Improvements in the preparation of chromic acid. December 12.

22,844. T. H. Copley. Improvements in treating waste substances for the production of potash, potash salts, water glass, founders' blacking and manure. December 12.

23,156. T. B. Greenwood. A new or improved infusion or solution for scouring and removing grease, size, or the like from textile fabrics. December 16.

23,201. J. C. Butterfield. Improvements in the treatment of brimstone and other sulphurised ores. December 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

21,464. F. M. Lyte. Production of chlorine in the purification of lead, in the recovery of precious or other metals with which the lead may be associated, and means or apparatus employed therein. November 30.

1892.

610. F. Valentiner. Process and apparatus for the manufacture of concentrated nitric acid. November 30.

1439. I. S. McDougall and J. T. McDougall. Treatment of certain corrosive or poisonous liquids to render them capable of being transported, stored, or used with less danger than hitherto. December 14.

1642. O. Imray.—From M. M. Rotten. Manufacture of sodium and potassium bichromates. December 7.

19,180. J. M. Milnes and A. Milnes. A new process or means for the production of chloride of lime. December 21.

19,213. I. Levinstein. Improvements in the method of and apparatus for concentrating sulphuric acid and other liquids. December 7.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

APPLICATIONS.

20,656. W. Oakes and J. Oakes. See Class IX.

21,945. E. P. Lee. Improvements in kilns for burning bricks, tiles, and other clay goods; also for burning sanitary ware and for salt-glazing. December 1.

21,951. W. Allen. Improvements in the manufacture of porous earthenware pottery articles for electrolytic purposes. December 1.

22,376. W. P. Thompson.—From R. S. Pease, United States. See Class X.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

20,115. L. West. Manufacture of plate and other glass, and apparatus therefor. November 23.

1892.

18,448. P. Sievert. Process and means for manufacturing glass pipes. November 30.

19,395. P. A. Moreau. Production of ornamental stones artificially coloured. December 7.

20,656. W. Oakes and J. Oakes. See Class IX.

23,181. J. Hamblet, jun. An improvement in paving bricks. December 16.

23,192. J. H. Blakesley. Improvements in fireproof floors, roofs, girders, joists, and the like. December 16.

23,235. O. J. Owen. Improvements in the utilisation of slate. December 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1892.

50. P. A. Moreau. Manufacture of artificial marble. December 7.

736. T. J. Davey. Chamber oven for drying clay from slurry or any other materials of a similar nature in brick or cement works. November 23.

14,889. R. Kieffert and H. Thiron. Cements. December 21.

18,575. H. J. Haddan.—From F. D. Cummer. Process of drying and disintegrating clay and similar materials. November 23.

18,803. K. Alsdorff. Improvements in fireproof walls and ceilings. November 30.

19,813. O. Böklen. Process for making cement or cement mortar. December 7.

19,908. C. G. Pickling. Fireproof buildings. December 14.

19,947. W. Gutmann de Gelse. Process for preserving timber. December 14.

20,414. P. A. Moreau. Manufacture of variegated or veined artificial stone and imitations of natural marble. December 21.

20,656. W. Oakes and J. Oakes. Kilns for bricks, lime, and the like. November 23.

20,832. F. von Hünnersdorff. Bricks or blocks for building purposes. November 23.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

20,656. W. Oakes and J. Oakes. Improvements in kilns for bricks, lime, and the like. Complete Specification. November 15.

20,832. E. von Hünnersdorff. Improvements in bricks or blocks for building purposes. Complete Specification. November 17.

20,963. H. Pfähler. See Class X.

21,037. J. W. Stansfield. Improved composition suitable for paving slabs, path surfacing, and for blocks, also stair threads and the like. Complete Specification. November 19.

21,064. H. Lockwood. An improved composition for flooring or covering iron bridges, arches, tanks, and other structures. November 19.

21,105. P. J. Jackson. An improved system of street or floor paving. Complete Specification. November 21.

21,486. H. Parry. Improvements in kilns for burning lime. November 25.

21,640. K. S. Meyer. Process for the manufacture of artificial building and other stone. Complete Specification. November 26.

21,851. J. Ferguson. Improvements in or relating to fireproof building construction. November 30.

22,004. F. W. Löhrmann. Improvement in the manufacture of artificial building materials. December 1.

22,784. J. Gaskell and W. Robinson. Artificial stone, bricks, tiles, and the like. December 12.

X.—METALLURGY, MINING, Etc.

APPLICATIONS.

20,547. T. Harris and H. C. Saeré. See Class XIII.

20,608. J. H. S. Bradley and R. G. Henchley. A non-corrosive metal alloy. November 15.

20,715. A. Macdonald. A new or improved process for treating silver and lead ores. November 16.

20,879. C. King. Improvements in the extraction of gold and silver. November 17.

20,900. E. Bailey and J. D. Massey. An improved process of manufacturing and depositing spongy lead for secondary or storage batteries or receivers. November 17.

20,963. H. Pfähler. Improvements relating to binding metal for use in constructions of concrete, cement, or the like. November 18.

21,053. A. Guthrie and R. F. Macfarlane. Improvements in the treatment of complex metallic ores. November 19.

21,085. A. S. Ramage. Process for pickling metals, especially iron for galvanising and tinning, whereby no waste substance is produced and no iron lost. November 21.

21,108. C. Allen, J. Clark, and G. W. Clark. Improvements in or relating to the manufacture of aluminium and alloys thereof. November 21.

21,162. R. Haddan.—From F. Singer and H. Barthel, Germany. An improved method of soldering aluminium and other metals, and an improved solder therefor. November 21.

21,202. P. Robinson. Improvements in the manufacture or production of channelled or troughed iron, steel, and other metals. November 22.

21,228. W. Tatlow.—An improved method of recovering tin from tin scrap or waste tinned iron. November 22.

21,271. E. Norton. Improvements in the process of tinning iron and steel plates. Complete Specification. November 22.

21,826. H. L. Sulman. Improvements in or relating to the treatment of ores containing zinc and antimony. November 29.

21,828. W. H. D'Avidge Cleminson. Improvements in the manufacture of pig iron from iron ore. November 29.

22,324. A. E. Tucker. Improvements in iron and steel manufacture. December 6.

22,369. W. J. Freeman and E. Freeman. Improvements in the manufacture of soft metal castings. December 6.

22,376. W. P. Thompson.—From R. S. Pease, United States. Improvements in apparatus for handling or working molten substances, such as metal and glass. Complete Specification. December 6.

22,600. W. R. Renshaw. Improvements in the treatment and hardening of armour plates. December 9.

22,601. W. R. Renshaw.—From F. G. Bates, United States. Improvements in converting iron or low-grade steel into high-grade steel. December 9.

22,672. H. H. Lake.—From H. A. Harvey, United States. Improvements in the manufacture of armour plates. December 9.

22,778. R. A. Carrasco. Improvements in galvanising iron and other sheets and in apparatus therefor. December 12.

22,843. W. R. Taylor. Improved application of aluminium and its alloys. December 12.

22,907. S. Wood. Improvements in the method of and apparatus for hardening and tempering steel wire for cards and other purposes. December 13.

23,020. P. Fowler. An improvement in the manufacture of iron and steel. December 14.

23,062. J. Moseley. Improvements in and connected with the processes of hardening and tempering steel wire. December 15.

23,169. J. Johnson.—From T. S. Blair and T. S. Blair, jun., United States. Improvements in desulphurising iron and steel. December 16.

23,194. J. C. Butterfield. Improvements in the treatment of tinned iron for the recovery of the tin and other products. December 16.

23,288. A. Longsdon.—From F. A. Krupp and Co., Germany. A new or improved process and apparatus for or relating to the manufacture of armour plates. Complete Specification. December 16.

23,286. P. M. Justice.—From J. Meyer, Grand Duchy of Luxemburg. Improvements in the manufacture of steel or ingot iron. December 17.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

13,796. H. Pilot. Iron silver. November 23.

17,621. H. W. Wallis. Concentration of pyritic ores. December 21.

19,860. Compagnie des Hauts-Fourneaux Forges et Aciéries de la Marine et des Chemins de Fer. The manufacture of steel. December 21.

19,928. A. Figge. Manufacture of iron, steel, or copper, and a material to be used in the said manufacture. November 23.

21,950. W. P. Breeding.—From the Ajax Metal Co. Improvements in the cleaning and preparation of metallic sheets and other articles, and in the coating of same with lead or alloys of same. November 23.

22,501. I. S. McDougall. Furnaces for burning ores containing sulphur and sulphur compounds. November 30.

1892.

1273. W. Hutchinsonsoo. Manufacture of iron and steel. November 23.

1341. T. Twynnam and J. Colley. Manufacture of steel and iron. November 30.

1467. C. Moldenhauer. Process of recovering precious metals from their ores. November 30.

1530. G. W. Clark. Manufacture of steel. December 7.

1654. C. Hopfner. Extraction of silver. November 30.

1776. W. Hutchinsonsoo. Manufacture of iron and steel. November 30.

1901. T. C. Fawcett and T. C. Fawcett, jun. Cupolas or furnaces for melting iron. December 7.

1907. W. Muir. Extraction of tin and other products from the refuse slags and debris of tin-smelting furnaces. December 14.

2261. B. Rösing and H. Foerster, and K. Foerster. Extraction of lead and apparatus therefor. December 21.

3237. R. A. Hadfield. Manufacture of cast-steel projectiles. December 7.

11,297. J. P. Bayly.—From J. J. Naeff. Process of recovering tin from tin scraps. December 21.

18,082. C. D. Abel.—From Hoerder Bergwerks und Hütten-verein. Process for the removal of manganese from pig iron, ingot iron, and steel. November 23.

20,208. W. A. Briggs.—From J. W. Richards. An improved solder for aluminium. December 21.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

20,598. C. Therye and A. Oblasser. Improvements in and relating to the manufacture of electric accumulators. November 14.

20,900. E. Bailey and J. D. Massey. See Class X.

21,074. F. C. James. Improvements in galvanic batteries. November 19.

21,193. G. E. Cassal and F. A. Kjellin. An improved method of producing zinc from blende by means of electrolysis. Complete Specification. November 22.

21,348. W. Wright and J. B. Hamond. Improvements in the treatment of zinc produced by electrolysis. November 23.

21,554. R. E. Disher, R. H. C. Hall, and C. Crockford. Improved manufacture of battery plates, and employment of ingredients therefor. November 25.

21,696. T. L. Willson. Improvements in electric smelting of aluminous and other refractory ores or compounds. November 28.

21,701. T. L. Willson. Improvements in the reduction or treatment of refractory metallic compounds by electric smelting. November 28.

21,794. E. Andreoli. Improvements in the manufacture of electrodes for ozonisers. Complete Specification. November 29.

22,344. W. Walker and F. R. Wilkins. Improvements in galvanic batteries. December 6.

22,375. W. P. Thompson.—From C. L. Coffin, United States. Improvements in the method of welding or working metals electrically. Complete Specification. December 6.

22,657. J. G. Lorrain.—From M. Dumont, France. A new or improved electric accumulator. December 9.

22,760. J. A. Heap. Improvements in the method of and apparatus for electrolysing aqueous solutions of salts. December 12.

22,950. R. Haddan.—From R. Gabarro, Spain. An improved galvanic dry battery or cell, and a composition for use in such cells. Complete Specification. December 13.

22,987. P. M. Justice.—From W. W. Griseom, United States. Improvements in secondary battery plates or elements, and in the process of preparing same. Complete Specification. December 14.

23,007. W. Walker and F. R. Wilkins. Improvements in galvanic batteries. December 14.

23,051. E. A. Mitchell and G. T. Tagwell. Improvements in galvanic dry cells. December 15.

23,101. C. A. J. H. Schroeder and H. E. R. Schroeder. New primary batteries. December 15.

23,232. J. Y. Johnson.—From A. M. Michel, France. Improvements in and relating to secondary or storage batteries. Complete Specification. December 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

18,597. E. Andreoli. Electrolysis. December 7.

20,413. G. Bamberg. Electrolytic apparatus, more particularly applicable for manufacturing caustic soda and other products from salt, but also applicable to other purposes. November 23.

22,030. C. Hoepfner. Electrolytic treatment of copper and silver ores. December 14.

22,854. F. Placet and J. Bonnet. Electrolysis of metals. December 14.

22,855. E. Placet and J. Bonnet. A method of extracting chromium by the aid of electrolytic baths with a base of salts of chromium. November 23.

1892.

1061. E. Hermite. Bleaching and disinfecting starch and fecula by electrolysis. December 7.

1141. C. Vogt. Dry electrical elements. November 30.

1786. R. Pinna. Tanning by electricity. December 21.

16,262. C. A. Faure. Electrolytical decomposition of alkaline chlorides for the production of chlorine and alkalis, and apparatus therefor. December 7.

17,169. C. Kellner. Electrolytical decomposition of metallic salts, and apparatus therefor. December 14.

17,224. W. P. Thompson.—From C. L. Coffin. Apparatus for electrically heating and working metal. November 23.

18,516. E. N. A. Picard and J. A. Taudière. Electrodeposition of metals. December 14.

18,844. H. Koller. Improvements in dry cells or galvanic batteries. December 14.

19,655. H. G. O'Neill. See Class II.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

APPLICATIONS.

20,682. R. Haddan.—From J. W. Evans, United States. Improvements in percolators for extracting oil. Complete Specification. November 15.

21,414. J. Kennedy. An improved soap. November 24.

21,809. G. J. Epstein. See Class III.

21,817. J. D. Barnett. Improvements in the process of cleaning and extracting oil and grease from cotton waste and other fibrous materials. November 29.

21,996. E. Hunter. An improved compound to be applied to driving straps. December 1.

22,039. H. H. Lake.—From G. Schlicht, Austria. Improvements relating to the manufacture of soap. Complete Specification. December 1.

22,137. E. Görg. Process for the manufacture of soda-potash soap. December 3.

22,322. W. C. Shaw. Improvements in the method of and apparatus for refining or bleaching oils and varnishes. December 6.

22,605. P. Zacharias and J. Gruawald. Improvements in the manufacture of soap. Complete Specification. December 9.

22,681. S. Stanton.—From E. W. Stanton, United States. Improvements in petroleum or naphtha soap and in the method of and apparatus for producing the same. Complete Specification. December 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

22,413. W. Saint-Martin. See Class XVII.

1892.

11,173. E. Noppel, B. Grosche, and T. E. Tack. Apparatus for purifying oil and separating new oil from drippings. Applicable also as an oil tank. December 21.

18,527. J. Brown. Manufacture of soft soap. December 7.

18,533. J. Brown. Manufacture of hard soap. December 21.

20,682. R. Haddan.—From J. W. Evans. Improvements in percolators for extracting oil. November 23.

XIII.—PAINTS, PIGMENTS VARNISHES, AND RESINS.

APPLICATIONS.

20,547. T. Harris and H. C. Sacré. The utilisation of a certain waste oxide of iron in the manufacture of paints and pigments, and for other purposes. November 14.

20,891. R. Matthews and J. Noad. Improvements in the manufacture of white lead and coloured pigments. November 17.

21,240. W. B. Lawson and H. Schofield. An improvement in the manufacture of liquid black lead. November 22.

21,370. C. Carron. Improvements in apparatus for mixing and automatically weighing white lead and similar powdered substances. November 23.

21,424. F. G. Groenert. A new or improved cleaning and polishing composition specially applicable for cleaning and restoring furniture, leather and the like. November 24.

21,639. J. Horadam. Improvements in the manufacture of water colours. November 26.

21,932. J. S. P. Stutley. An improved composition paint. Complete Specification. November 30.

22,098. F. Crane.—From J. Crane, United States. Improvements in or relating to paints and driers therefor. December 2.

22,099. F. Crane. An improved manufacture of filler or coating for wood surfaces. December 2.

22,175. W. Baker. The manufacture of an improved composition for waterproofing and other purposes. December 3.

22,322. W. C. Shaw. See Class XII.

23,206. R. Ripley. An improved or new manufacture of black lead. December 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

22,391. R. B. Johnson and T. C. Palmer. Manufacture of white lead and apparatus therefor. November 30.

22,809. M. Williams. Manufacture of oil paints and paint medium. November 23.

1892.

790. W. Smith. Manufacture of white lead by the acetate of ammonia process, more especially in respect of the regeneration and recovery of acetate of ammonia from the weak liquors and washings furnished in the process. November 30.

1882. D. Swan. Obtaining pigments. December 7.

22,011. R. I. Clark. Manufacture of varnish. December 21.

13,240. H. Pfanne. An improved method of and apparatus for treating linseed oil to obtain a product applicable as a varnish. November 23.

14,888. R. Kieffert and H. Thirion. Paints. December 14.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATIONS.

20,677. M. Heftler and G. Bénard. Improvements in or relating to the extraction of tanning and dyeing materials. Filed November 15. Date applied for May 17, 1892, being date of application in France.

21,551. T. Cowburn. Improved process of and apparatus for tanning and cleaning hides and skins. November 25.

22,480. A. Sinan and H. Sinan. A process for clarifying or decolorising tannic extracts. December 7.

23,233. J. M. E. Foutenilles and H. G. J. R. Baguenier-Desormeaux. Improvements in purifying and clarifying tannic liquids. December 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1892.

838. S. Thorn. "Substitutes for tannin of an article in substitution of what is commonly known as tanned leather." November 30.

11,521. L. Munk. New or improved manufacture of material suitable for use as a substitute for whalebone. December 7.

XV.—AGRICULTURE AND MANURES.

COMPLETE SPECIFICATION ACCEPTED.

1892.

3806. E. Groe and E. Ramond. A composition for dressing vines and other trees. November 28.

XVI.—SUGARS, STARCHES, GUMS, Etc.

APPLICATIONS.

21,038. L. E. Asser and L. A. H. Hartogh. Improvements in the manufacture of starchy material. November 19.

21,217. W. P. Thompson.—From F. Soxhlet, Germany. Improvements in or relating to refining sugar. Complete Specification. November 22.

21,939. W. P. Thompson.—From F. Schiaffino, Italy. Improvements in the treatment of raw sugar for purifying and drying the same. Complete Specification. November 30.

COMPLETE SPECIFICATIONS ACCEPTED.

1892.

3241. A. G. Brookes.—From. F. Paetow. Refining or purifying sugar. December 14.

11,972. W. Hannah and F. Curtis. Improvements in the method of manufacturing sugar in cubes or other forms, and in means or apparatus to be employed therein. December 14.

XVII.—BREWING, WINES, SPIRITS, Etc.

APPLICATIONS.

20,684. F. W. Wright. Improvements in and apparatus for effecting the raising and aerating of beer and other liquids. November 15.

20,773. A. Jenik. Improved construction of dephlegmators or apparatus for condensing and separating aqueous constituents and impurities from alcoholic vapours. November 16.

20,787. F. M. Polsky. Improvements in the manufacture of yeast. November 16.

20,825. H. Stock. Improvements in germinating apparatus. Complete Specification. November 17.

20,903. R. H. Leaker. Improvements in distilling and rectifying brandy, whisky, and other spirits, and oils, essences, and the like, and in machinery and apparatus therefor. Complete Specification. November 18.

21,284. H. H. Leigh.—From B. C. Batcheller, S. D. Schuyler, and W. M. Cramp, United States. Improvements in process and apparatus for drying brewers' grains. Complete Specification. November 22.

21,661. H. Reid. Yeast fermenting cakes. November 28.

21,897. C. S. Meacham. Improvements in means employed in the preservation of hops. November 30.

22,253. K. R. Geduld. Process for artificially acidifying yeast-mash. December 5.

22,495. W. Shreeve. An improved method or process of dressing and cleansing beer, wine, or other barrels or casks. December 8.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

22,413. W. Saint-Martin. Means or apparatus for maturing and improving fermented alcoholic liquids, applicable also for oxidising oleaginous and other liquids. November 30.

1892.

911. R. H. Leaker. Method and apparatus for kilning malt. November 30.

17,927. R. Ilges. Improvements in the method of and apparatus for distilling mash for the purpose of obtaining highly concentrated fusel oil and purified alcohol. December 21.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

APPLICATIONS.

A.—Chemistry of Foods.

21,091. J. Dudin. See Class XX.

21,111. P. F. Shaw and A. W. Orr. A new mode of preparing extracts of meats and like substances. November 21.

21,488. W. Paterson. A new or improved process in the manufacture of bread and the like with extract of malt. Complete Specification. November 25.

21,623. G. D. Dennis. An improved process of preserving dried vegetables. November 26.

21,637. G. Dierking. Improvements in or relating to the enriching of milk and other beverages. November 26.

22,068. J. J. Clark. Improvements in the manufacture of starchless flour and bread. December 2.

22,115. M. Julien and A. Brin. A process of enriching milk and producing cream and butter. December 2.

22,189. G. C. Legay. An improved process for the sterilisation of milk. December 3.

22,733. J. H. Cayless. Improvements in or relating to the manufacture of bread. December 10.

22,831. J. Swan. Improvements in preserving eggs. December 12.

22,922. A. J. Boulton.—From L. Fromm, Germany. A method of preserving farinaceous products. Complete Specification. December 13.

23,230. E. J. Daviond. Process for removing bad flavours and odours from vegetable or animal products without affecting their active or nutritious qualities. December 16.

B.—Sanitary Chemistry.

21,215. J. Swallow. Improvements in or relating to the means or process for treating and clarifying sewage and other impure or polluted waters. November 22.

21,291. A. O. Jones. Improvements in the treatment and utilisation of sewage and plant therefor. November 23.

22,458. J. Hanson. Improvements in apparatus for burning town refuse or like objectionable matter. December 7.

22,530. J. M. Allan. Improvements in the method of and apparatus for the treatment of sewage or the like. December 8.

22,766. T. Brown. An improved system of intercepting and separating solid from liquid sewage. December 12.

C.—Disinfectants.

20,785. S. Pitt.—From Schloessing Brothers, France. An improved insecticide and anticyptogamic composition for the treatment of plants. Complete Specification. November 16.

COMPLETE SPECIFICATIONS ACCEPTED.

A.—Chemistry of Foods.

1891.

20,436. W. P. Thompson.—From Moser and Co. Improvements in and connected with the process of extracting cocoa or rendering it soluble for the preparation of soluble cocoa, or the manufacture of cocoa powder, chocolate, or the like preparations. November 23.

1892.

1150. K. G. Krikorian. A new or improved method of treating and roasting malt, and blending the same for infusion together with coffee. November 30.

1717. S. Saker and W. C. Glover. The manufacture of a compound for use in preparing infusions of tea. December 11.

C.—Disinfectants.

1891.

22,258. C. C. Leathers. A new or improved apparatus for disinfecting or odourising purposes. November 23.

1892.

5036. J. B. Dewhurst. An improved compound for disinfecting and other purposes. December 7.

XIX.—PAPER, PASTEBOARD, ETC.

APPLICATIONS.

21,485. E. Cadoret and E. Degraide. A new or improved process of manufacturing incombustible and inodorous celluloid. Complete Specification. November 25.

21,795. E. N. Cummings. Improvements in toilet and wrapping paper. Complete Specification. November 29.

21,948. J. P. H. Huesser. The new blotting and filtering paper. December 1.

COMPLETE SPECIFICATION ACCEPTED.

1892.

3103. F. T. Jefferson. Manufacture of paper for the copying books of manifold writers for making tracings and for other like purposes. December 14.

XX.—FINE CHEMICALS, ALKALOIDS ESSENCES, AND EXTRACTS.

APPLICATIONS.

20,548. F. Keller. Improvements in menthol cones. November 14.

20,903. R. H. Leaker. See Class XVII.

21,091. J. Dudin. Improved process or method for the manufacture of tea extract and apparatus therefor. November 21.

21,938. F. Krafft and A. Roos. A new process of preparing methyl-ether, ethyl-ether, and their homologues by the action of alcohols on benzenesulphonic acid and other sulphonic acids or their esters. Complete Specification. November 30.

22,442. O. Murray.—From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Manufacture of peptones free from albuminous matters. December 7.

22,757. J. F. F. von Mering. Improvements relating to the production of acetyl and propionyl compounds of *p*-oxyphenylurethanes or their ethers. December 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1892.

1438. I. S. McDougall and J. T. McDougall. Treatment of solutions of arsenic or of salts of arsenic for diminishing the danger incidental to their transport. December 14.

1808. J. Berlinerblau. Manufacture of para-phenetol-carbamide and para-anisolecarbamide. December 14.

1946. H. Boisselier. A new combination of eucalyptus and its products. December 7.

2194. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik. The treatment of amido-guanidine for the manufacture of a new compound and products derived therefrom. December 21.

3147. A. Bang.—From G. A. Dahl. An antipyretic and anti-nenralgic chinolin derivative, and processes for the production of the same. December 7.

XXI.—PHOTOGRAPHIC PROCESSES AND MATERIALS.

APPLICATIONS.

21,442. F. Hes. Improvements in toning photographic prints and negatives. November 24.

21,622. H. W. Vogel and J. Weinberg. A new or improved paste for the prevention of discoloration of photographs mounted upon Bristol-board. November 26.

22,576. J. Hauff. The employment of diamido-dioxybenzol in combination with sulphides of the alkalis for developing the latent image in layers containing halogen silver for photographic purposes. December 8.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

21,381. J. T. Sandell. Manufacture of sensitive plates for photographic purposes. November 23.

1892.

4498. J. Hauff. A process for developing photographic images. December 7.

XXII.—EXPLOSIVES, MATCHES, Etc.

APPLICATIONS.

20,880. A. H. Durnford. An improvement in the manufacture of explosive and other compounds containing dissolved nitrated cellulose. November 17.

21,058. A. McDougall. Improvements in the manufacture of explosives. November 19.

22,023. A. Kramer. The "gigantic" explosive. December 1.

22,739. H. Kolf. Improvements in the manufacture of gunpowder. December 10.

22,992. H. C. Seddon. Improvements in percussion fuses for projectiles. December 14.

23,105. O. Inray.—From C. Glaser and Co., Germany. Process for manufacturing powder suitable for practice ammunition, sporting cartridges, and similar purposes. December 15.

COMPLETE SPECIFICATION ACCEPTED.

1892.

6258. O. Inray.—From M. M. Rotten and Co. Manufacture of explosives. December 7.

XXIII.—ANALYTICAL CHEMISTRY.

APPLICATION.

23,109. W. Belgrove. An improved means of testing the quality of milk. December 15.

PATENT UNCLASSIFIABLE.

APPLICATION.

21,452. W. F. Greene. Improvements in the preservation of perishable articles. November 24.
